Agreed, liquid electrical tape needs to have a more resilient quality when dry. Not tough enough to handle any "bumps & bruises" in handling. The plasti-dip they sell in small pint & quart cans for dipping tool handles in to give it a rubberized coating works better, and last's longer. Got my last can at H. Freight for about $6. Used it anywhere I had to splice coax runs with a barrel connector and PL-259's. Oldest is 14+ years...no problems yet.

Very good practice. Learned this trick when I was in a radio/tv broadcasting course in high school (way back in the md-late 70s). after the course that day, the teacher said he better not find tangled cords again in the supply room or that person would receive an F for the course final (don’t really know if he meant it, but nobody took him up on it).

I installed VERY thick power cables in the industry

When we had to lay out a longer and thicker cable on the ground we made a "figure eight" ... same thing ... no tangling and no turn in the cable

If you ever had to lay out a 4 x 185 sqmm (or thicker!) and then pull it the rest of the way you absolutely do not want a turn in the cable (or it will not lay down flat on the cable truss)

Such thick cables are almost as stiff as tube/pipe ... and a turn in that cable and YOURE LOST (and big boss will give you a kick in the a..)

Same thing in the TV industry - camera cables were 2" in diameter roughly.. (they carried power, monitor signals, control lines,a nd 3 video channels each in their own coax inside the fat cable. Probably about 80-100 conductors in the cable. And they were fragile.

If not figure-8'd properly, 1: they would not go back in the truck properly... 2: they would not come out of the truck properly 3: it would take a crew of 4 people to try to untangle the suckers when trying to set up to cover a baseball game or whatever. Now, they are digital, and either a lot smaller, or just carrying power, with RF carrying the back haul to the truck. but they STILL get figure-8'd...

I have been trying to make a 4:1 Balun that works down on 3.7mhz
I am usung the Guanella type wound on unknow toriods (2x 8turns)
I have produced 3
but on testing them with a MFJ analysier and only carbon resistors (100ohm) across the unknow
am am only able to get the swr down around 2:1, the swr does go lower the higher in frequency.
Do i need a particular core? do i need non iductive resistors?
or need to buy a proven balun?

ps I thought the inductance would show it self at the higher frequencies and swr grow at higher frequencies

Thanks for any advice you may
post

Hi,

What type of power is this balun for and what is the purpose of the balun (ie antenna is it for). It would be handy to know for advice on cores etc. Cores do matter as they are frequency dependent on the material used.

Umm 100R via 4:1 gives 25R so 2:1 SWR is about right - yes?

Or have I missed something here?

Two resistors in series for 200ohms, correct?

> am am only able to get the swr down around 2:1, the swr does go lower the higher in frequency.
> Do i need a particular core? do i need non iductive resistors?

Yes. Carbon composites are supposed to be OK. But they're hard to find,
I think.

> or need to buy a proven balun?

No. Be a ham. Make one. Do you have a book?

>

Sounds like you need more inductance at low frequency: increase the
number of windings or change out the core for one of higher permeability.
If more windings won't fit, you can split this design of balun over
two cores. What sort of wire are you winding with?

If you're making a 4:1 balun and testing it with a 100 ohm resistor, the transformed impedance would be 25 ohms (100 / 4). It shouldn't be surprising that you get around 2:1 SWR.

Try it with a 200 ohm resistor. 200 / 4 = 50, which should give you a low SWR on the analyzer.

73,
Frank

Are you making the resistance 200 ohms? you say 100 and multiple
resistors. but youre not clear if you actually have 200 ohms on the
unit. 100 ohms would be 2 to 1

32105. RE: [ham-antennas] What am I doing wrong?

Yahoo group: ham-antennas (2014)
Date: 2014-04-20 22:42:21 UTC
From: Richard Schmuke
Topic: 32097 Message: 32105

I make the Guanella type baluns all the time, when following the “book” I get a sweet spot of low SWR at about 10MHz and have to add a few turns of wire to move the low SWR to a lower frequency for a 160/80 balun.

http://i1102.photobucket.com/albums/g453/KD0ZZ/2rod.jpg

The resistance needs to be 200 OHM , carbon or non-inductive. You cannot check one by its self as they are just a 1:1 balun then crossed at one end making a 4:1. You can put a switch between the baluns at the input end and make it a 1:1 or 4:1 switchable balun.

http://i1102.photobucket.com/albums/g453/KD0ZZ/EndView-1.jpg

Subject: [ham-antennas] What am I doing wrong?

I have been trying to make a 4:1 Balun that works down on 3.7mhz

I am usung the Guanella type wound on unknow toriods (2x 8turns)

I have produced 3

but on testing them with a MFJ analysier and only carbon resistors (100ohm) across the unknow

am am only able to get the swr down around 2:1, the swr does go lower the higher in frequency.

Do i need a particular core? do i need non iductive resistors?

or need to buy a proven balun?

ps I thought the inductance would show it self at the higher frequencies and swr grow at higher frequencies

Thanks for any advice you may

32106. 2 Large Ceramic Antenna Insulators - NEW

Yahoo group: ham-antennas (2014)
Date: 2014-04-20 22:46:03 UTC
From: <kz3dx@...>
Topic: 32106 Message: 32106

This is a pair of NEW Ceramic porcelain glazed antenna insulators. These are Industrial/Commercial/Marine grade insulators. The size is 1 1/2 inches by 2 1/4 inches. They can be used with wire or cable up to 7/16 inch.
For antennas or guy wires.
I am going to try to post a picture in the Photos section.
Price is 2 for $11.95 with FREE SHIPPING in the lower 48 states.
Please email me at: kz3dx at yahoo.com
Thanks,
Bill KZ3DX

What do you guys recommend for specs for ferrite rods used to make baluns. I have made them with torrid cores but would like to make some with ferrite rods just not sure what type and size for lets say rated to 1.5kw…..Also what gauge magnet wire would you recommend…

Hello,
I wanted to let you know that I've modified the plans posted at http://ve3elb.ham-radio.ch/2m-70cm%20antennas.html for use with copper piping and a di-electric insulator and made an instructional video you can watch at http://youtu.be/60NQ4ZKoooA. The swr was under 1.5 and so far the antenna is working great.

32109. UHF / VHF / HF Antenna : your input please much appreciated.....

On the HF:

I'm somewhat biased, but you'll not do any better at the price point and in a 25' vertical than the Butternut, and I've tried a lot of verticals. But be realistic about your expectations on 75M. When it comes to HF, there is no substitute for physical size. It does very well on 40M and above. The other nice thing about it is it doesn't use traps, so it is lightweight and not top heavy. All the weight is near the bottom. You can add the WARC bands to it later if you wish, but it requires a retune when you do. But you MUST use radials.

I'll let others comment on UHF/VHF.

> <http://www.diamondantenna.net/d130j.html>
```

Wideband antenna that has no gain on vhf/uhf

I would use a dualband stacked vertical like x300 (or similar)

All these stacked verticals just have ONE MAJOR problem!!! All connections in these antennas are crimped (and most of them are wiggling even when brand new) ... so additionally soldering them is a good idea (complete dismantle the antenna and solder ALL crimped connections)

```
>
> HF
>
> .
> http://www.bencher.com/ham/index.php?main_page=product_info&cPath=4&produc
> ts_id=13
> <http://www.bencher.com/ham/index.php?main_page=product_info&cPath=4&produ
> cts_id=13>
```

The butternut is a very good antenna but needs a good radial-field below to work fine (as every ground mounted antenna)

```
>
> . http://www.diamondantenna.net/cp6ar.html
> <http://www.diamondantenna.net/cp6ar.html>
>
```

Traps add losses in the antenna (all traps in a row on lowest band) ... so I would not use that

And ... cp6 has no warc bands ...

...

Why do you wanna go vertical on shortwave?!? ... no way for installing a dipole or loop?!?

....

Buy some good antenna books :-)

Dg9bfc

Sigi

Ps I would install a ladderline fed loop or dipole ... and maybe a 43 feet vertical with autotuner at the base

This antenna works quite well for what it is: rather short for bands below 20, but still OK. It is a 3/8 wave antenna on 20 and pretty much requires a certain length of coax as a matching section.

> ? http://www.diamondantenna.net/cp6ar.html

This one is much too short: to my mind, all it is is an expanded mobile whip with loading coils.

Probably all right in an emergency, but certainly not one I would choose for a home station antenna.

OK, I am going to chime in too, as I have been playing with antennas since
1979 or so. Until this last Spring, I had not ever bought a HF antenna
accept for some converted CB antennas for 10 meters. However, your choices
are (gasp!) expensive! I have seen people use an Eagle One with a tuner,
and spend less than any of these HF antennas. I have slung up antennas that
cost a few dollars, tuned to all bands, and worked the world with them.
There is a nice alternative to the expensive Diamond Discone on eBay that
will cover your little rig just fine, see
here<http://www.ebay.com/itm/121319915539?_trksid=p2055119.m1438.l2649&ssPageName=STRK%3AM
EBIDX%3AIT>.
A discone is wasted unless you are going for the 900 mhz band or 1240. The
857D won't go there...

I do not believe in spending more than I need to, even on antennas, but if
you have deep pockets and can afford it, these will all do a good job.

May as well jump in. Apparently you are trying to get one antenna that will do it all. Maybe I am stupid, but I have not encountered or built an antenna that will cover everything. I have a Horizontal dipole that covers from 160 to 6 meters, and I have seen tons of home made VHF/UHF antennas, j-poles, etc. Nothing in my experience has ever shown me one antenna that can do all bands well. Even with an antenna tuner, the HF antenna does not also cover the VHF/UHF bands well if at all. Normally the HF and the VHF are far enough apart that they do not do well on one antenna. As with all things I suppose there is an exception to the rule out there somewhere. But it sounds like your looking for two antenna’s to cover all you mention. These two could be inexpensive compared to a lot of the big bad factory models. I have a home built Vertical made from a CB antenna and ground mounted. I use a 4:1 UNUN and it tunes pretty well from 10 through 40 meters. With further adjustments I feel it will be able to cover 80 meters as well. The point is that it still takes two antennas to cover these very different bands. Less expensive or outrageous, the same holds true as far as the ones I have played with. You are certainly welcome to do your shopping or home brew building as your thoughts dictate. But for the less expensive but useful antennas, two would seem to be what you need

I would just like to add my 2 cents. I have experimented with some of these vertical antennas as an experiment. Their performance is somewhat disappointing and setup is a nightmare. The butternut antenna is very tuning sensitive, bandwith is very tight, you still need lots of radials, unless you park it at 30' above ground. It has since been sold to someone else. What I myself have done is look at what I want to do within the hobby, and be selective. I have separate antennas for 2 meter and 440, A separate Texas 6 meter antenna. And a 33' S-9 with a 4:1 Unun for my HF antenna.
I went separate on the VHF/UHF antennas to get a greater range of bandwidth. That allows me both repeaters and Simplex. Same reason for the separate 6 meter antenna. My HF vertical is 33' because I live in an HOA. The antenna is hidden from prying eyes by 2-40 foot trees. I have had great success with this antenna, I have a limited area for radials, but was able to get down about 16 at 12 to 33 feet long. I also constructed 3 Petlowany coils to further help both transmission and reception. I have talked around the world with it, literally from Russia to South Africa and Patagonia to Finland and lots of places in between.
The one thing that I have learned is this. There is no one antenna that can do it all. Join a club, go to meetings, make lots of ham friends and pick their brains. Every area of the country has its own unique set of circumstances, areas like blackholes, soil conductivity problems, and the list goes on. Then apply what you have learned to your situation and grow from there. Thanks
Dave W9CAC

This is just my point of view. Nothing is simpler than a VHF/UHF vertical. It can be as simple as a SO-239 and some wire.

http://i1102.photobucket.com/albums/g453/KD0ZZ/DSC00811.jpg

The picture is a close up of one of many I have made, you can make a 1/4wl 2M vertical antenna and add a 440 stub and operate on two bands. I use stainless steel wire for its stiffness but copper will do. Some nay-sayers will claim stainless is hard to solder but with a little flux it is no problem. Here is a picture of my 1/8" SS wire with a 1/16" upper section of the same antenna, it was done for looks as I did not want to buy a tapered wire and a full 19" of 1/8" wire looked a little clunky,
http://i1102.photobucket.com/albums/g453/KD0ZZ/DSC00812.jpg

For HF start with a simple dipole and add from that point. A fan dipole can cover as many bands as you want. Here is a picture of one installed that cover 6 bands.
http://i1102.photobucket.com/albums/g453/KD0ZZ/DSC00812.jpg. Today I am using a loop that covers 9 bands.

Nothing sounds or hears better than a homemade antenna, IMHO.

Rich, Kd0zz

There is an antenna project planned for a five story steel frame apartment in the city. The proposal is to use a SGC 239 coupler feeding a 45 foot vertical aluminum roof top mast. The coupler would be located at the base of the vertical mast where the connection to the building's steel frame is available. Building administrators will allow no wires on the roof so there is no opportunity for radials or counterpoise.
The thought is that long mast will pick up a lot of static during summer electrical storms and winter snow storms and maybe a balun at the feed point would be an advantage. The other proposal is a heavy RF choke across the feed point to the ground connection. The operator is active from 3.5 to 29 Mhz. and the coupler allows her to operate this range of frequencies on her present indoor 40 metre dipole. Comments and experiences would be appreciated. Thanks, 73

I do not understand the thing about a heavy RF choke, but...
a 45 foot vertical should work fine from about 40 meters up, and fair on 80
and 60. It will have a low angle of radiation on 20 and up, so will be good
for DX, but it will have to have an antenna tuner.

Have fun

Hi Natarajan,

I own and use a Bencher Butternut HF9V which is the 9 band version of the HF6V. It is a good physically short vertical for 6 through 80, and will work in a limited fashion on 160. Carefully read the installation instructions regarding mounting, as ground mounting requires an extensive ground radial field for the antenna to be effective. If it is on a mast or roof it will require some form of lengthy counterpoise system cut to resonant lengths for the bands you intend to work. Or, it can be mounted on a large area of metal roofing as long as the area is large enough to create a reflective ground plane.

The HF9V is also resonant on 2 meters and works very well on FM vertical polarization, so with a bit of creative cabling and a very minor amount of tuning you can use it on that band. Never checked the HF6V, but would expect it to be very close to the HF9V on 2 meters.

One thing to consider with the Bencher Butternut antennas is that they are not easy to tune. It takes a great deal of time and effort with a decent antenna analyzer to properly set one up and have it actually perform where it should. Another consideration is wind, they do not take kindly to high winds and will require maintenance. I repair mine after every 80 mph wind, and then have to retune it to bring it back into my usable frequencies. My opinion is that they are excellent vertical antennas, but maybe not for the person just starting out as they can be quite daunting and labor intensive.

If available in India, I would consider the Zero-Five 6-80 meter ground plane vertical for a new HF vertical antenna installation, they require no tuning, go together in a very short time, and have a very effective ground plane system built into them when properly mounted. They have much better wind resistance than the Butternut. They also cost much less than the Butternut and are far more durable.

I have used the CP6AR and would not recommend it to anyone for any purpose if they had to pay for the thing. I got mine for free and ended up scrapping it to use in a homebrew project, and it was great for that!

The Yaesu 857D is a 160 through 6 meter rig in the States, with 2 meters and 70cm included. If the version available in India has the ability to use 23 and 33cm bands, then it may be useful to acquire the Diamond Discone. But, if you are looking at the same frequency availability on that rig in India as in the States, I would look for a much simpler dual band antenna, or build my own vertical or horizontal dipoles for 2 meters and 70cm.

Best of luck,
Randy

I have used an RF Amp plate choke as a static drain and "usually" disconnect the ant in the station if not home or a storm comes by. Fortunately we get few lightening storms here on the Pacific coast of Ecuador but lots of rain and wind so the static drain helps.
Yes, I know that lightening will vaporize it so that is why I disconnect inside. Haven't had one vaporize yet in 60 years but still play it safe.

Jim,

The General Class Amateur Radio License does not expect anyone to know anything.
The license examination itself is nothing more then a primer.
The questions on the test exposes the operator to a smorgasbord of topics and gives you a little exposure to those topics.

The old hams that wrote the test uses this as a way to identify those that are unwilling to study and learn.

The test itself is nothing more then memorization.
A person that has a good memory can identify the questions and pair them up to the right answer and regurgitate the right answer just long enough to get the license.

The antenna book shows you how to build a simple antenna.
Lets take the G5RV for example.
The G5RV is a very poor resonator.
It's creator - Louis Varney took that design to the grave with him, because it bothered him so much that it didn't work especially well - anywhere except 20 meters.

When the G5RV was designed, the transmitters used tubes and the matching networks were very robust..
A Johnson Matchbox is a good example.
Un-knowledgeable hams often times exclaimed that you could tune up everything from a bed bug to the London bridge as long as you used a piece of ladder line..

It was the coaxial cable that caused all the problems for the hams that came along after the golden era of ham radio.

The only thing the antenna book will teach you is how to layout and build a antenna.. The rated gain of the antenna and the lobe angle expected from the antenna at X height.

The take off angle of your signals and the signals you wish to receive is very important.

Everything pertaining to radio is all about Location, Location, Location....

Being in the highest place gives you a great take off angle and offers you the most signal available, but also increases the noise level..

Its not always advantageous to have the highest antenna or live in the highest elevations.

NVIS can be a very good antenna if you do not want to work DX, and just want to listen locally - up to 500 miles - which is what most hams does anyways.

My Elmer once said there are two kinds of antenna's, the kind that works and the kind that does not!

Dave,

Today's research involves designing small antenna's for shorter wavelenght's cell phones in particular.
I know when I did some research on the previous Chancellor for Dubois Penn State - Ping Werner, Ping and her husband holds 3 US Patent's for antenna's...

Ping teaches a basic electronic's 101 class at Dubois Penn State...

As far as technology goes, amateur radio is very old technology and mostly under rated as anything but a novelty in today's academic world.

In the DEF building in Dubois they have on display a old World War II aircraft transmitter and receiver - ARC 5..

As long as Amateur Radio is being portrayed as people using this antiquated technology - we are not going to entice younger people to this hobby.

The schools themselves - other then government grants and high tech companies giving the schools grant money to invent these new technologies - this stuff is all going by the wayside...

The only thing that schools and kids cares about today is cell phones and Ipods and I pads and lap top computers and what is in it for them...
You can mention most any video game to most any IT student or instructor and they can hold a intelligent conversation for hours but ask them the most simple question about two way radio and they are in the dark.

The schools are getting rid of the older books and most everything is going digital... Even the text books are mostly obsolete.

I like this .....I have been a Ham for 35years and about 10 years ago while explaining something to a new Ham I admitted that when I licensed I knew nothing. It took a long time for me to realize that those things that I remembered from my cramming were being used daily & those I could not quite remember I knew were there and where to look them up for whatever I was doing. Soon I realized I knew what I had memorized so many years ago . Never scorn a feller that took whatever it took to join in with us .....Chuck Wq5B

A complete understanding of antennas is a very complex task for any one not in the field of designing antennas. Making a simple dipole to start with is the way to go. The more you build the more you will learn. Back in the late 70’s I bought a CB radio because everyone else had one, I then mounted it on my motorcycle, a very odd move back then. Most antennas were made for the top of a car or truck, I needed something different , as I researched what was available. I then found two school of thought , CB radios seem to spawn some very strange ideas and people and could not work on their equipment.. I found another group of “radio” people the had some idea of my problem. Talking with the people in the antenna development lab I found most of them were also amateur radio people. They sent me in the right direction and a found a antenna for a fiberglass boat is what I needed and opened a door to what has been a life time of enjoyment. I feel very comfortable today with antennas but it did not come with a test or piece of paper but buy building things. Gone are the day of building your own 100 watt plus radio from the local parts emporium but building your own antenna and QRP rigs are very much alive.

Put up a dipole and enjoy it, if you are into VHF make a copper J-Pole for 2M, it’s easy, has gain and you will enjoy being able to say I made it myself. You can make the same J-Pole with some wire taped to a broom stick. After a few builds it will all be clear.

I found that when I travel, the 6" dummy load wasn't a very good antenna when in an all steel framed hotel room, no matter what floor I was on...so...some TV 300 ohm twin lead, an SMA connector and a 6 foot length of RG-175, soldered to the TV lead, that had one lead cut to frequency, ie: a j-pole, and a hook at the top, clipped to the curtain rod in the hotel room, turned my 5 watt HT into a great radio for all the local repeaters. Best part, was when it was time to leave, it rolled up into a small bundle that fit into my radio and electronics go-bag. it would even go into my briefcase and not interfere with any paperwork inside!

You are right with that statement, though spending money you do not have is like trying to swim without any water to do so in. That is the case of the majority of hams I know, the money is not there to spend for any reason or price, regardless of want or need.

I am heading towards my fourth year licensed and totally agree that you just need to be good at memorizing and nearly anyone can pass all the tests.

However obtaining the license is really only the first step in exploring what is an awesome hobby and adventure in continuous learning. The real exploration for me has been in rediscovering my old electronics technician training from my Navy days and my SWLing hobby when I was a kid.

Now I build homebrew antennas using books like the Antenna Compendium, the ARRL Antenna Book, Low Band DXing,and the Internet etc. I think antennas are the most fascinating part of the hobby for me. And experimentation starting from building the simplest dipole to building homebrew 6m yagis, or K9AY receive antennas or homebrewing slopers for low bands has been more rewarding for me than all the commercial bought and installed antennas that I have owned.

I actually enjoy the antenna projects almost more than I do operating. It is funny how that happened. This is a great yahoo group where I have also learned a lot.

Too bad it's on display: I use those, receivers and transmitters, regularly here. As far as I am concerned, the ARC-5 receivers were the absolute finest single-band receivers ever produced. Aircraft Radio Corp included several true geniuses amongst its staff.

> As long as Amateur Radio is being portrayed as people using this antiquated

This "antiquated technology" has many features which are still valuable today: like being EMP proof....

> The schools themselves - other then government grants and hig h tech companies
> giving the schools grant money to invent these new technologies - this stuff is
> all going by the wayside...

Sadly, yes. The young are not taught that just because something is "old" doesn't mean it is worthless.

Although this is WAY off topic, I'll mention it anyway to illustrate my point: some time ago, I sold a Collins R-389 VLF receiver to a fellow who worked at a University in the midwest in the Mechanical Engineering Department. The receiver was shipped to his lab at the U where he worked. When it arrived, his female work-study student watched him unpack it and then stated, "What do you want THAT old thing for?"

Then he plugged it in, turned it on, and operated the tuning mechanism.

Her eyes bugged out as the tuning racks moved up and down and the motorized dial spun and she didn't say another word, but she spent almost the rest of the day operating the receiver while trying to figure out how the designers did what they did and why.

All my buyer did was smile and watch her.

Unfortunately, even digital technology may not appeal to the younger folks.
The will say that it's like the Internet. If they want to contact a
friend at a distance, they can go on Facebook or send an e-mail or a
text message.

When I grew up in the 50s and 60s, ham radio was a big deal because of
the ability to reach others who were possibly on the proverbial other
side of the world.
Long-distance phone calls were expensive, so if you received one it was
probably bad news - i.e. "Uncle Albert died this morning."

When I first started maintaining air traffic control radar systems in
the Air Force, there were probably 100 or more controls per channel to
adjust for an alignment.
The newer replacements for the tube-based systems had many fewer
controls, and the need for alignments was less frequent.
One piece of ancillary equipment had only one adjustment - the 5V p/s
voltage!

Needles to say, I lost interest in pursuing a civilian career with the
FAA when I left the Air Force at the eight-year point.

Commercial Antenna options exist because some people are just not
mechanically inclined.
The only commercial antennas I have owned were mag mount 2 meter and 440
antennas.
The 440 mag mount started life as a scanner antenna till I converted it
to work as a 1/4 wave 440 antenna.
The 2 meter was a 5/8 wave that I still use but was given to me.
All of my base antennas aside from my antron99 are homebrewed.
Of course I was just give a 10 meter hygain 5 element yagi not to long
ago but it isn't up in the air yet and I haven't made up my mind if I
want to put it up yet either.

Antennas are not that hard to build or experiment with, just do some
research and get out the tools.
:)

32139. [PRB1] Poway California Amateur Radio Antenna Ordinance Developments

Yahoo group: ham-antennas (2014)
Date: 2014-04-25 16:02:33 UTC
From: rick darwicki
Topic: 32139 Message: 32139

This is a short summary of
subject.

As some of you know, Poway hams are in the
2nd year stretch of trying to get the City of Poway to enact an amateur radio antenna ordinance that gets
the city into compliance with Federal and California state amateur radio regulations. If you are not familiar with our two year effort, I will be pleased to bring you up
to speed, off this reflector.

We are nearing the conclusion of the
campaign. On May 6th, the
Poway City Council will hold what is known as a "workshop" where the public can
express their comments regarding a proposed city ordinance. The proposal will
shortly be publicly distributed.

We have it on very good authority that the
City Council is already of a mindset to give us what we asked for, a simplified
permitting process for an antenna support structure up to 65 ft high, and then a
streamlined process for someone who wishes to go
higher.

This as contrasted with the current
"practice" that, in Poway, there is no such thing as an antenna structure (or
anything for that matter) higher than 35 ft PERIOD (unless grandfathered from
before the city incorporated 30 years ago. Most of those have now fallen
down).

This has all come about through raising
political awareness among Poway hams, including
support of ham-friendly council aspirants for the last election, careful
lobbying of the city council since that time, and an excellent legal campaign
carried out with the assistance of counsel.

Poway hams presented the city council with
a very extensive technical analysis (SME paper) that scientifically and
empirically justified the 65 ft height as an acceptable compromise lowest height
for a permitted antenna (not requiring other than a building permit). The paper
addressed the totality of amateur radio's purpose, and addressed all matters
associated with propagation practice and prediction.

The principal and only opposition to all
of this has been driven by a local non-profit organization called the Green
Valley Civic Association (GVCA). They purport to speak for "all Poway residents". In
actuality, they are a very small

group influential (moneyed) real estate agents who were instrumental in the incorporation of the City, brought a large number of high tech companies to the Poway business park, and have close ties to
some city council members. They have "run" the city for many
years.

In the run-up to this next City council
meeting, GVCA went out and contracted a study to demonstrate that "35 ft high antennas are adequate for amateur radio communications".

Please find attached the result of the
GVCA effort.

From a depth of technical analysis
perspective, this paper is laughable.

The saddest part is that the paper is
authored by PHD electrical engineer and Extra class amateur radio operator. Poway hams assume the paper is scoped to meet
the resources GVCA had available, and the author was not presented with the totality of purpose for which the GVCA hoped to use the paper. GVCA is not flush with funds.

Powayhams are NOT concerned about refuting,
if necessary and in a devastating manner, the technical aspects of this material.

Likewise, the paper will be analyzed with
counsel as preparations are made for one-on-one discussions with Poway City Council members BEFORE the council meeting.

I offer the paper in question for
appropriate comments from the PRB-1 perspectives.

Powayhams can use all the help we can
muster.

The cell phone and power distribution infrastructure in this country are great but they are not entirely immune to the effects of earthquakes. I'm not sure where Poway sits with respect to one of the big fault lines but wouldn't it be nice if hams with sufficient antenna height were able to provide effective emergency communications to the region in case of emergency?

Rick, I don't see an attachment nor as ny notification that a file was uploaded to the group. I'd like to read it. You can send it direct if you wish or, for others to look over as well, you can upload it to the files section.

Sounds like it has been quite the battle. Here in Seattle we (Amateurs) are limited to 50' (max) antenna structures and, depending on where you live in the city, some aren't even allowed that high.

32142. linear amp question

Yahoo group: ham-antennas (2014)
Date: 2014-04-25 22:50:42 UTC
From: Yazen Aswad
Topic: 32142 Message: 32142

Dear all:

I am very new to radios, have a question about linear amplifiers. I bought two from ebay, they have been set on [2M] 140-150Mhz

I installed both in two different cars, installation was simple and straightforward. Each one of them connected to Baofeng UV-5R and antenna of course.

Issue I am facing:

When radio in car A transmits, nothing is being heard on the other radio in car B but it can be heard on other radios not connected to amps.

Car B can hear car A only when the amp is turned off in car B, and vise versa, car A can hear car B only when the amp in car A is turned off.

When TX on either amps I hear clicks in the amp.

I tried talking to some folks on the local repeater, they could hear me very well, but I couldnt hear them when they talked back, could hear them on the third radio which isnt connected to amp.

Car A and B are at least a mile away from each other while testing!

Seller confirmed that both amps are new! they look new to me. Installation was simple, connect to power, antenna and radio! nothing less nothing more.

There must be something wrong somewhere, can you guys assist me please, any suggestions, advices and guidance would be highly appreciated.

Many thanks,
Yazen

32143. Re: [ham-antennas] linear amp question

Yahoo group: ham-antennas (2014)

From: Kenneth G. Gordon
Topic: 32142 Message: 32143

What ever you are using to key the amps is keying them on continuously, and they are NOT turning off when you "unkey".

Normally, when an amp is "keyed", an internal relay disconnects the antenna from your receiver and connects the antenna to the amp output.

Normally, when any amp is "unkeyed" it reverts the antenna back to the receiver. In your case, that is not happening.

Your antenna is staying connected to the amp...or at least, the antenna is NOT being connected to the receiver.

When you turn the amp off, all switching reverts back to normal, and your receiver works, because now it is connected to an antenna.

A couple of questions:

1) What is the EXACT make and model of the amp.

2) How are you keying it? Simply by the RF emitted from the Baofeng?

3) What is your location?

4) What is your call and class of license?

On 25 Apr 2014 at 17:50, Yazen Aswad wrote:

> straightforward. Each one of them connected to Baofeng UV-5R

HOW did you connect the Baofeng to the amp? What sort of cable did you use? Where did you connect it? Did you connect an RF cable AND a control cable?

You say this:

> When TX on either amps I hear clicks in the amp.

How many clicks? When? Do you hear ONE click when you key the Baofeng and another when you "unkey" the Baofeng?

Yazen: WE here on the group need more information.

1. Whose amplifier's are they (Make?) 2. Do they have a switchable pre-amplifier (for the receive side,) in the amplifier? If not, I suspect the relay is bad that switch's between Transmit & Receive. If so, suspect the pre-amp for the condition's you set.

Can't advise any further without knowing WHO made the amp's (so I can look up the schematic's,) and IF they have pre-amp's in them,

OK. That is correct.

Next, I did not get the link to the amp you bought, so I need that.

Secondly, it SOUNDS as though the amp has an RF actuated changeover relay, as another member posted, the relay may be bad.

However, without seeing the amp's schematic, we can't help much.

Thank you for your response.

I am not sure if it has a switchable pre-amolifier or not. Attached is the diagram which came with the device.

Brand name is: HYS
Model: TC-150
Frequency: VHF
Input power: 1-5 Watt
Output power: 50 Watt

Thank you once again,

Wearing blinders about technology is nothing new.

A long time ago, I worked in Florida for a C-SPAN-like project.

Another tech was a recent college grad, and was a whiz at television technology.

I took him on a tour of the local telephone company. He was AMAZED at the fact that it was possible to send 1200 telephone conversations simultaneously on one microwave carrier.

And yes, the current generation is very iPod (and like device)-centric. I work as a sub, and the regular teachers often give up on getting the kids faces out of the screen. To get a room quiet for some work, the teachers let the kids listen to music on their "devices". Whereupon, the kids spend more time picking the next tune than they do working on the school work. And no, they are not skilled at multitasking, although they claim to be.

THank you for the schematic. That pretty much answers all MY questions. It DOES have an RF actuated switch which uses TWO relays to switch from RX to TX and back.

There is no receiver preamp either.

You have it connected correctly.

It looks to me as though one of the two relay switching circuits is not working or is locked in the TX position.

Secondly, since JR1 is delayed to open or close AFTER JR-2, you SHOULD be hearing TWO clicks, even if the clicks are very close together, BOTH when you key and unkey the rig, not just one.

At this point, I suspect that either 1) capacitor C5, obviously an electrolytic cap, is shorted, and that SW-1 is in the "ON" position, or 2) C29, the other electrolytic which is connected directly to the base of Q-1 is shorted. If either of those capacitors was shorted, Q-1's base would be grounded, which would turn on JR1 permanently, and the RX would never be connected to the antenna.

The purpose of SW-1 is to add C5 to the circuit to delay the relay opening.

I would switch SW-1 to the "other"position, and try it. If you then hear two clicks on each operation of the push-to-talk switch on the Baofeng, then the problem is C5. If there is no difference, then the problem is a shorted C29.

It is also possible that Q-1 is shorted and the capacitors are OK.

An additional test. Since it does not have a preamp, you should be able to put an ohm meter from the center conductor on the input and output and see continuity on receive mode.

Odd. The photo shows THREE switches on the front, but the schematic shows only TWO.

What happens if you switch ONLY that switch that turns the light on, but leave the other TWO off? OFF is with the bottom pushed in, ON is with the top pushed in.

Try that and get back with us.

It is possible that the third switch, not shown on the schematic, bypasses the other relay...

Sure.

BTW, after examining your photo of the amp with the cover off, either Q-1 and Q-2 are mounted on the BOTTOM of the board, or that schematic is for a different amp!

Neither Q-1 nor Q-2 nor C5 are on that board: at least not on that side of it.

Ken

Okay here is what I found:

I switched on only one switch.

I could hear two clicks, very close to each other, when keying and unkeying to PTT.

Cars were about 0.5 mile away from each other and could hear each other really well with no issues whatsoever!! But stopped hearing each other when they were about 1 mile away from each other.

I dont have my ohm meter with me at the moment! will get it back on money [friend borrowed it!!]

Thank you very much gentlemen.

Well, in addition to what I mention below, there is also the fact that the front panel shows three switches, and the diagram only shows two.

I really think they sent you either the wrong amp, or the wrong diagram.

From: <email4utoo@...>
Topic: 32156 Message: 32156

i want to take my rig ,(argo ten tec 556 5 watts), portable so i have been reading and experimenting with wire antennas, so i wanted to try out some time tested ,(funny but many old timers have used this stuff with success)- TV 300 ohm oldtime Twin lead - Radio Shack that is on clearance . I soldered the ends of the Dipole twin lead together, cut it 67 .5 ft. ,(for soldering , cut mistakes -Murphy's Law rules in this case ,hihi), wanted this antenna for 40-10 meters . The Feedline is , yes -Twin Lead -run into my ZM-2 Emtech- then coax to my Xcvr. I wanted to just check matching and hearing level etc, so i placed the antenna up only about 4ft on those plastic Electric Fence posts we have used them for our Family milk cows , (yah we make our own cheese, that is another story , hihi)
Not expecting much i flipped on the Argo started tunning Forty meters - BOOM ! What super loud SSB and some CW ! Band was Quiet ! What happened ! so i looked at my lap top for info on my Gidget i downloaded for Solar info on my Desktop - showed Band Quiet ! I was so tired from other work i have not had time to put it up today higher or compare with my OCF , hihi. Oh what a shock that was at 4ft ! i thought i found the perfect portable antenna ! Maybe it is will know more as weekend goes on - by the was the feed length in case it was bugging you is the remainder of the 100ft roll of Twin Lead- about 32.5 ft i kept it above ground to the shack. It tuned very well on 40 and even better on 10 meters , so i am Jazzed and excited . Let me know if you have built one of these and how it went , AJ KF5ZYB-(used to live in large metro city ,now a rural Hillbilly enjoying no HOAs or city restrictions , hihi) yes and very low taxes). 73s and 2s

PS i very well could have gotten this design from the Files section here which are many and have spent many a late hour reading and studying them - i do not take any credit - this Design is an oldie but goody.

32159. Tower question

Yahoo group: ham-antennas (2014)
Date: 2014-04-26 15:48:04 UTC
From: bcarling@...
Topic: 25 Message: 32159

Guys
I have a need for some advice about a small simple tower.

I am looking at putting up a small beam for HF (A3WS Cushcraft) which is about 4 sq ft wind
load. Need your advice,. I ONLY want to put it up 24 - 30 feet above ground to clear the roof
over our two story house. I am not climbing on the roof. I want to avoid guy wires and can get
LIMITED support from a bracket to the gutter. Hip pocket roof and the eaves are recessed
under the roof edge quite a bit, and not easily accessed for strong support points.

So basically I was looking at something like an aluma 25 footer or a Delhi 28 foot from
Canada. They are around $600 which is close to affordable... otherwise something like two
sections of Rohn 25G plpus a mast. I know there are a few options in towers of that size.
Ideally it would be free standing, no guy wires, and have a tilt over base - maybe even
homebrew the tilt mechanism, and walk it up or pulley it up into place at some point along the
support structure of the tilt over.

I would like to hear from experienced fellas out there. I have only done two towers before.
The first was a 60 footer, braced against the house and with two sets of guys. My lot is too
small for that here. The second was only 30 feet, (plus mast) and out in the open with one
set. Both used Rohn 25G with a gin pole etc. I need to keep this simple, inexpensive and not
too strenuous for an old guy.

The mast at the top can add some height. I will measure the actual distance to the peak of
the roof but it has to be around 22 or 23 feet.

My friend has a nice looking homebrew hinge plate at the base of a tower, and looks like it is
made of angle iron painted with rustoleum for protection.

> that transistor???

Sigi:

If you look carefully, you will see that that circuit, with Q-3, is ONLY IN the circuit when the amp is in the transmit condition. Therefore, it has to be some sort of driver for the final amps.

Also, if you look at the photo that was sent of the open amplifier, you will see that Q-3 is obviously a VHF transistor of some sort.

The relays are shown in the receive condition: i.e., bypassing the Q-3 circuit.

Therefore, that is NOT a preamp.

At this point, it also appears likely that that schematic is not the correct one for the amp that is the subjece of this discussion: the schematic shows only two switches, whereas the amp has three, and the board photo does not show Q-1 or Q-2 or C-5, although they COULD be mounted somewhere else...

32161. End-Fed random wire antenna

Yahoo group: ham-antennas (2014)
Date: 2014-04-26 18:16:33 UTC
From: <schwartzj22@...>
Topic: 32161 Message: 32161

To all:
I want to put in an end-fed wire for receiving only. My house is a rectangle, 60 feet by 25 feet. I am planning to install this antenna on the house about 6 to 10 feet high. Since the perimeter is 170 feet I have the option to run a wire at any length up to 170 feet. I have also run calculations and determined what lengths to avoid for the frequencies that I will be using. I will use a good tuner but no balun. This receiving antenna will be used with an SDR receiver.

My questions are:
1) What configuration is best (but attached to my house) for optimum signal reception for 80 - 10M? Any articles I could read for receive antennas? Specifically on theory of wire antenna orientation and optimum receive signals?
2) If I do transmit at low power, can I use the same configuration as for receive?

Any help is appreciated,

Joel - N3GSE

> I'm not Sigi, but it's not wired that way,

I disagree: it is wired so that Q-3 is included in the circuit in the transmit mode, by JR-2 (or JR-1), which is operated by Q-1 (or Q-2: I don't have the schemo in front of me right now) which is operated by the RF input to the RF-sensing switch. Q-1 and Q-2 are essentially in parallel. If that "extra switch" was to turn the preamp on and off, it would be connected somewhere OTHER than where the contacts of JR-2 are "bypassing" Q-3.

The schemo shows the amp in the receive mode, and Q-3 is bypassed in that mode.

Besides, if that extra switch was to turn a preamp on and off, why are both JR-1 AND JR-2 shown and labeled very clearly on the circuit board itself as shown by the photo of the opened amp? If the switch was what bypassed the preamp, the entire circuit would be wired differently.

Also, if Q-3 is a preamp, why is the transistor obviously a VHF transmitting transistor?

I agree with you about a preamp: they are almost never necessary.

I agree with Bill: use your perimeter (I assume you mean, the perimeter of your property line) to run a loop completely around it.

Since you are going to use a tuner, I think you will find a loop of much more value than an end-fed, especially one that low.

And it WILL work as a transmitting antenna too, although, most likely, as an NVIS one.

Nonetheless, TRYING it will tell you far more than asking here.

Billy, Ken, Sigi,
Great input-thanks. I will have to read up on loops but maybe it is simple and I do not have to. For a loop I think all I have to do is the following but please correct me if I'm wrong.

The loop would be attached to my house which is 60' by 25'. I think all I would need is a single 170 foot length of wire and run the two ends into my shack under my window sill. Ladderline is not an option. The loop would not be symmetrical but would be about 170 feet. I think I should connect to a tuner with its balanced line connection and its internal 4:1 balun. Is this correct?

Originally I was thinking end-fed and would use ¼ wave counterpoise wires for each band. For the end-fed I did calculate the best wire lengths so as to avoid multiples of a half wave length. For the loop, are there any preferable lengths to use and if so how do I calculate this for 10 – 80 meters?

Tks,
Joel – N3GSE

Joel,

Google the formulas they are a few on line for loops. But you want a loop for the lowest band. The key with a loop is as big an area in the middle as possible. A resonant loop is around 100 ohms at feed point. However if yours is a non resonant loop I usually use a 4;1 balun with them for multiband use and never had any issues with it. Forget ladder line anyway.

Joel

Maybe you should try something else which is a very simple antenna and good for DX.

Nothing new really, everything has been tried in the past by someone.

Before I always used the W3DZZ in my globe trotting A 10 to 80 metre antenna and only 108 foot long.

Well that□s too long for my backyard at this QTH so I thought lets use half of it. So we are now down to 54 foot.

Even better lets go vertical and along.

So I hung one end on my gutter which was about 20 foot and then horizontal and down 20 foot. That gives me an overall distance of 34 foot.

Most people can do that.

It has worked a treat and I have been working all over the world with my 25-50 watts.

Since then I have got the vertical section up to 32 foot and then the trap is attached and come off horizontal for 20 foot.

The really good thing is you can go straight in with 50 ohm coax.

I am just waiting for some tubing to come so that I can get the vertical section up to 40 or 50 foot. I then intend to put a 75/80 metre trap on the end and about another 20 or so foot.

The G3VIR Trap L is born!

One thing about this without going into all the technical details. You do need a counterpoise or radial system to make it work at full potential.

Of course you can always put a 1:1 balun at the feed point too.

A couple of my local friends have now made this antenna and they are delighted with theirs.

I hope this gives you more food for thought.

Roley G3VIR

Subject: [ham-antennas] Re: End-Fed random wire antenna

Billy, Ken, Sigi,

Great input-thanks. I will have to read up on loops but maybe it is simple and I do not have to. For a loop I think all I have to do is the following but please correct me if I'm wrong.

The loop would be attached to my house which is 60' by 25'. I think all I would need is a single 170 foot length of wire and run the two ends into my shack under my window sill. Ladderline is not an option. The loop would not be symmetrical but would be about 170 feet. I think I should connect to a tuner with its balanced line connection and its internal 4:1 balun. Is this correct?

Originally I was thinking end-fed and would use ¼ wave counterpoise wires for each band. For the end-fed I did calculate the best wire lengths so as to avoid multiples of a half wave length. For the loop, are there any preferable lengths to use and if so how do I calculate this for 10 – 80 meters?

Tks,

Joel – N3GSE

Subject: [ham-antennas] Tower question

Guys
I have a need for some advice about a small simple tower.

I am looking at putting up a small beam for HF (A3WS Cushcraft) which is about 4 sq ft wind
load. Need your advice,. I ONLY want to put it up 24 - 30 feet above ground to clear the roof
over our two story house. I am not climbing on the roof. I want to avoid guy wires and can get
LIMITED support from a bracket to the gutter. Hip pocket roof and the eaves are recessed
under the roof edge quite a bit, and not easily accessed for strong support points.

So basically I was looking at something like an aluma 25 footer or a Delhi 28 foot from
Canada. They are around $600 which is close to affordable... otherwise something like two
sections of Rohn 25G plpus a mast. I know there are a few options in towers of that size.
Ideally it would be free standing, no guy wires, and have a tilt over base - maybe even
homebrew the tilt mechanism, and walk it up or pulley it up into place at some point along the
support structure of the tilt over.

I would like to hear from experienced fellas out there. I have only done two towers before.
The first was a 60 footer, braced against the house and with two sets of guys. My lot is too
small for that here. The second was only 30 feet, (plus mast) and out in the open with one
set. Both used Rohn 25G with a gin pole etc. I need to keep this simple, inexpensive and not
too strenuous for an old guy.

The mast at the top can add some height. I will measure the actual distance
to the peak of
the roof but it has to be around 22 or 23 feet.

My friend has a nice looking homebrew hinge plate at the base of a tower,
and looks like it is
made of angle iron painted with rustoleum for protection.

From: Jeffrey Lord
Topic: 10944 Message: 32175

I an thinking of erecting a 4o mt loop antenna with A 10 mt inside
Yard area is only 15 x 12 meters and I have 4 extendable pipe masts that will give me 7-8 mt height for the antennas
I currently use MFJ 941E tuner but I am looking at a T tuner as the MFJ has seen better-days
Any thoughts please

Jeffrey

A loop will work well with your 10w. Ditch the ladder line tho and feed it with 50ohm coax going to a 4:1 balun. A square loop will be fine. I gas a loop up at my house triangular shape only 6m of the ground and it worked very well on 40m. I don't know how well your loop design will work on 80m but will work well on 40-10m. I had a ldg tuner which handled the loop fine so your tuner should be good.

I think you live on a very tiny property

Not much room on 12x15m for antennas

40m loop will not work (good) on 80

If your transmission line is say 50' or less, then ditching the ladder line may be ok. That's a decision you'll have to make.

The higher the swr on the coax, the higher the loss.

Google the article " the lure of ladder line".

Many run coax. Many more run ladder line to a Balun under the eave and coax thru the wall. I ran it all the way to a Palstar tuner.

With the loop, Imwas thinking of a 40mt loop and a 10 mt loop inside , I am wondering what if the 2 loops would interact with each other , and if they would act as either reflectors and or directors for each other???
Also I Have a J pole for 2mt &70cm which seems to work well , however I think I should be getting better distance than I am .
Any suggestions on a home brew that will give better radiation & gain??
Thanks for the imput sso far and I will consider all comments , I do a lot on 80mt so really need an antenna that is efficient on that band.
By the way we live on a 609 sq mt block and they are a common size block in Australia, .

Cheers,

Lots of discussion about feed line loss and so on in the reflector and there is good information on the web.

The link below was in a email from the Topband group and I found it interesting and I want to share it.

It has nice graphs and detailed information that you should consider before spending your money on coax.

If you build a 40m loop ... it will work fine on 10 ... no need to box a 10m loop inside

A good antenna for 80m??? local (nvis) or dx???

Local would be a dipole or also a (horizontal) loop

Dx?? A vertical and an added rx antenna (k9ay loop or similar)

Totally agree,

One loop should be fine. If your looking for a dx antenna for 80m get a vertical. Even if you can only get it vertical for 8m then slope the rest to the ground that works just as well as a vertical.

Question,

A "Sky Lopp" antenna. Should it be resonant on the lowest band of interest? Or just make the thing as big as possible period?

Joe,

A resonant loop is better obviously. I would always make a loop a multiple example 80m loop works all the way to 10m if I couldn't get a loop for say 80m in my garden but I could for 60m I would make the 60m loop size. Rather than a radian size. That's just my opinion tho.

You really don't need two loops, especially if fed with ladder line. The losses on coax with a loop would be nasty, plus, tuning would be difficult. I use balanced line with a dipole, see MFJ-1777<http://www.mfjenterprises.com/Product.php?productid=MFJ-1777>, and have very good results, though it really does not like 160 - neither do I really. With my MFJ-993B tuner, it goes to 10, and with a LDG AT-100Pro][, it goes all the way to 6! With balanced line on your loop, you could make the loop for 80 and with a tuner work it through 10 or even up to 6 with no problems.

32187. RE: [ham-antennas] Tower question

Yahoo group: ham-antennas (2014)
Date: 2014-04-28 00:36:49 UTC
From: Van Lincoln
Topic: 25 Message: 32187

A few years ago, I used a tower in my backyard
which was 2-ten foot sections of Rohn 25G and 1-section of 10 foot 25G
half buried (5 feet in the dirt hole, threw in
about 4 bags of cement in a lower disc of concrete and an upper disk
of concrete at ground level, then the nice part
was the Beam and rotator were mounted on a Glen Martin Haxer Trolley
which went up and down up and down the side of
the 25G Rohn tower. Lastly, got a 6 foot heavy wall aluminum mast
on the rotator and bolted on my TA-33 Sr.

Worked great, was 1 foot below the roof ridge,
not visible from street, but climbable, and easy
to work on, thanks to the hazer.
TOtal cost was $650 used tower and used hazer and
used rotator, and used TA-33Sr.

Wasn't hard to put up after purchasing all the
parts needed in various hamfests.

Just an Idea for you.

a 40 meter loop will be matchable on 80, but the radiation will be very poor. (Lots of cancellation due to the size.)

However, it will do a bang up job on 40 through 10.

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

32189. Alex Loop vs Alpha Loop - The facts you should know

Yahoo group: ham-antennas (2014)
Date: 2014-04-28 01:41:27 UTC
From: <aa2nh@...>
Topic: 32189 Message: 32189

Alex Loop vs Alpha Loop - The facts you should know

Additional testing is encouraged, and I am sure needed. I have eliminated the differences that appear obvious to me (bands covered, options included, etc.). I will do my best to compare seven common criteria; 1) Durability, 2) Losses, 3) Weight, 4) Bandwidth, 5) Efficiency, 6) Tuning, & 7) Price.

1) DURABILITY
Alex Loop - Primarily constructed of Coax with PL259/SO239 connections & PVC with a variable air capacitor in a plastic box
Alpha Loop - Primarily Annealed/Soft Solid Aluminum with stainless steel bolts/nuts, with variable air capacitors in UL-Listed Weatherproof Outdoor Electrical Box
Winner - By a narrow margin, the Alpha Loop for their use of a UL-Listed Weatherproof Outdoor Electrical Box.

2) LOSSES
Alex Loop - Losses occur when coax is used in the construction of a magnetic loop antenna because the braid of the coax has thousands of connection points.
Additional losses occur at both of the PL259/SO239 where the coax attaches. Alpha Loop - Losses occur at 8 connection points.

Winner - I would like to see an end to end test done on the outer loop of each, measuring resistance and the like, so I will reserve judgement on the outcome till that is performed.

3) WEIGHT
Both the Alpha Loop without tripod and the Alex Loop weigh just under 3 pounds.
Winner - Tie

4) BANDWIDTH
Alex Loop - All we know from the manufacturer is that this loop requires retuning when frequency is changed. Individual analysis from other sources indicates:
28.004 (SWR at 2.2) to 28.060 (SWR at 2.1) around 60 Khz of bandwidth.
21.020 (SWR at 2.0) to 21.070 (SWR at 1.7) around 50Khz of bandwidth
14.000 (SWR at 2.1) to 14.035 (SWR at 1.9) around 35Khz of bandwidth
10.110 (SWR at 1.8) to 10.125 (SWR at 1.9) around 15Khz of bandwidth
7.005 (SWR at 2.5) to 7.015 (SWR at 2.6) around 10Khz of bandwidth

Alpha Loop - The manufacturer of the Alpha Loop (Alpha Antenna) is upfront with a scientific analysis from a RigExpert AA-54 antenna analyzer. Ref:
http://alphaantenna.com/pdf/Alpha_Loop_Analysis.pdf
"Unlike other magnetic loop antennas that require retuning because of narrow bandwidth, the Alpha Loop provides a generous bandwidth of approximately 35% of the 15 meter band, 85% on 17 meters, 20% on 20 meters, 100% on 30 meters, & 20% of the 40 meter band while maintaining an SWR of between 1.1:1 and 3:1. This is made possible because we do not use a coaxial shield or copper tube in the construction of the Alpha Loop Antenna. Rather, the Alpha Loop Antenna uses a specially selected aluminum alloy that has particular chemical properties to make it softer and have less resistance than 'rigid aluminum' tubing. The

minimally resistive properties and physical dimensions help to optimize the bandwidth and effected radiated power of the antenna. Additionally, we use only Brass Bolts and Nuts at the connection points that feed the antenna as well as silver plated shield and gold plated pin connectors on the SO239 at the feed point of the antenna to further decrease the resistance throughout the whole antenna system." ~ Alpha Antenna
Winner - Alpha Antenna

5) EFFICIENCY
Comparing the Alpha Loop & Alex Loop
I have spent much time inputting all of the variables into
http://www.66pacific.com/calculators/small_tx_loop_calc.aspx
http://www.66pacific.com/calculators/small_tx_loop_calc.aspx for the bands that are safe to operate both the Alex and Alpha Loop on, and found why the Alpha Loop has more gain.
The measurements from Alex for his loop are Length of Conductor (antenna "circumference") = 10.3 feet & Diameter of Conductor .32 inches.
Here are the calculated efficencies for the Alex and Alpha Loop antenna's. Please not that the Alpha Loop's measurements are Length of Conductor = 9.92 feet & Diameter of Conductor = .477

Antenna efficiency - The Alpha Loop VS the Alex Loop
From 7 to 7.3 MHz
Alpha Loop; 8% - 9%
Alex Loop; 6% - 7%

From 10.1 to 10.150 MHz
Alpha Loop: 23% - 23%
Alex Loop: 18% - 18%

From 14 to 14.350 MHz
Alpha Loop: 48% - 50%
Alex Loop: 41% - 43%

From 18.068 to 18.168 MHz
Alpha Loop: 69% - 70%
Alex Loop: 63% - 63%

From 21 to 21.450 MHz
Alpha Loop: 79% - 80%
Alex Loop: 74% - 76%

An alarming find when I input Alex's measurements for his loop into
http://www.66pacific.com/calculators/small_tx_loop_calc.aspx
http://www.66pacific.com/calculators/small_tx_loop_calc.aspx for 10 through 12 Meters occurred. On those frequencies a RED message appears that says:
"To avoid self-resonance, the conductor length for a small transmitting loop antenna should be less than 1/4 wavelength."
I now understand why the AlexLoop should not be used on 10 & 12 Meters, which is because exponential increases in resistance will occur on a small transmitting loop when self-resonance occurs, which can damage equipment.
For more information on this, see the section titled "Inductance and self-resonance" here:
http://www.antennex.com/preview/Dec03/Dec603/Loopantennas.htm
http://www.antennex.com/preview/Dec03/Dec603/Loopantennas.htm

6) TUNING
Bandwidth determines how often an antenna has to be retuned, so the Alpha Loop has a fair advantage over the Alex Loop from the start. When retuning is required, the 6:1 reduction drive in the Alpha Loop's MicroTune version makes it easy to declare the Winner - Alpha Loop.

7) PRICE
Alex Loop (antenna only) $366 Delivered. Ref http://www.alexloop.com/buy.html
Alpha Loop (Antenna Only) $295 Delivered* Ref https://amateurradiostore.com/all-alpha-antennas-c-2/15-to-40-meter-alpha-loop-jr-without-tripod-or-bag-xmt-rcv-p-272 https://amateurradiostore.com/all-alpha-antennas-c-2/15-to-40-meter-alpha-loop-jr-without-tripod-or-bag-xmt-rcv-p-272

Craig,

AlexLoop has a portable version which I own. I never considered the others as I am not aware of any portable units they make. The AlexLoop Walkman comes with a nice carrying case and setup time is 1-2 minutes.

Winner - Alpha Antenna

5) EFFICIENCY

Comparing the Alpha Loop & Alex Loop

I have spent much time inputting all of the variables into http://www.66pacific.com/calculators/small_tx_loop_calc.aspx for the bands that are safe to operate both the Alex and Alpha Loop on, and found why the Alpha Loop has more gain.

The measurements from Alex for his loop are Length of Conductor (antenna "circumference") = 10.3 feet & Diameter of Conductor .32 inches.
Here are the calculated efficencies for the Alex and Alpha Loop antenna's. Please not that the Alpha Loop's measurements are Length of Conductor = 9.92 feet & Diameter of Conductor = .477

Antenna efficiency - The Alpha Loop VS the Alex Loop
From 7 to 7.3 MHz
Alpha Loop; 8% - 9%
Alex Loop; 6% - 7%

From 10.1 to 10.150 MHz
Alpha Loop: 23% - 23%
Alex Loop: 18% - 18%

From 14 to 14.350 MHz
Alpha Loop: 48% - 50%
Alex Loop: 41% - 43%

From 18.068 to 18.168 MHz
Alpha Loop: 69% - 70%
Alex Loop: 63% - 63%

From 21 to 21.450 MHz
Alpha Loop: 79% - 80%
Alex Loop: 74% - 76%

An alarming find when I input Alex's measurements for his loop into http://www.66pacific.com/calculators/small_tx_loop_calc.aspx for 10 through 12 Meters occurred. On those frequencies a RED message appears that says:
"To avoid self-resonance, the conductor length for a small transmitting loop antenna should be less than 1/4 wavelength."
I now understand why the AlexLoop should not be used on 10 & 12 Meters, which is because exponential increases in resistance will occur on a small transmitting loop when self-resonance occurs, which can damage equipment.
For more information on this, see the section titled "Inductance and self-resonance" here: http://www.antennex.com/preview/Dec03/Dec603/Loopantennas.htm

6) TUNING

Bandwidth determines how often an antenna has to be retuned, so the Alpha Loop has a fair advantage over the Alex Loop from the start. When retuning is required, the 6:1 reduction drive in the Alpha Loop's MicroTune version makes it easy to declare the Winner - Alpha Loop.

7) PRICE

Alex Loop (antenna only) $366 Delivered. Ref http://www.alexloop.com/buy.html

Alpha Loop (Antenna Only) $295 Delivered* Ref https://amateurradiostore.com/all-alpha-antennas-c-2/15-to-40-meter-alpha-loop-jr-without-tripod-or-bag-xmt-rcv-p-272

*$275 before delivery plus avg CONUS price est. at $20

Reply: If using coax it will be better to get it resonant.

If ladder line , you don't need to fuss with it unless you want to.

Joe, I made my loop about 80M in size and adjusted the length for a good SWR in the middle of the 20M band. I use it 80M thru 6M.

M0MCX has a good YouTube on MMANA for this loop set up.

Yes I did the same with a grown tower that was guy and only buried about 2 feet of the bottom section in the ground. For a shorter, freestanding tower I would bury a larger part of the bottom section and maybe use one cubic yard of concrete or more in the hole.

I have seen freestanding run 20 5G towers that are quite tall. However I think it is only safe with a shorter tower. Especially somewhere like where I live in Florida.

Best regards - Bry Carling

32199. Loop Antennas

Yahoo group: ham-antennas (2014)
Date: 2014-04-28 14:48:24 UTC
From: <soona4sail@...>
Topic: 6496 Message: 32199

Loop antennas, are my favorite antenna. I am lucky enough to have enough room to build large loops (in excess of 1000 ft) but even smaller loops (40 mtr and up) work very well.

Couple of points: To get the most out of your loop, and to make it into a multiband antenna, it should be fed with a balanced line. My feedline comes down to a 4 to 1 current balun, just outside the shack window, then
short piece of coax, for convenience, thru the window to a tuner. My Elmer tells me to use a CURRENT balun,and NOT a voltage balun. Voltage baluns, according to him, are a sure fire way to guarantee RF on the outside of any coax in the system.

It is also important to avoid multiples of frequency wavelengths on your feedline. Google "Feedline lengths to avoid"

Finally, here is a link (not me) to one of the best loop antenna construction sites on the internet I have found.

http://www.k5rcd.org/hor%20loop%20instruct.htm
http://www.k5rcd.org/hor%20loop%20instruct.htm

Loop antennas, are simple, inexpensive, and work well. If you can, build your own open wire feedline, it is the best way to go. The twin leads, and open wire ladderlines, have their own set of issues, i.e. sometimes the wires breaks inside the insulation, and they are very susceptible to tuning issues when wet, frosty, or covered in snow.

Good luck and good DX
Soonasail

Here is an interesting question.

The 4 to 1 balun I do have, (commercial made one) OLD, ohh 5 years maybe? A W2AU made one. Now it is totally weathered, so there is no visible writing anymore.
Is there a way to tell if it is a current,, or a voltage one?

It'll be a voltage balun. It's the same OCF dipoles people say you need to use a 4:1 current balun. At my qth mine is a 4:1 voltage balun and u never have any rf issues on the coax. I can't remember how to do a test but I'm sure there's a video on YouTube showing you. (I would need to look)

I cannot explain why in a technical form but I know my antenna does not work as a square with good SWR points. Mine is a 80M size delta loop and has low SWR on all but 18 & 10Mhz but my internal tuner takes up the slack on those bands. I lowered my antenna one time because of a ice storm, raised it back up thru about 18” of snow and the readings were off because I had lost a support in a tree. I reset the shape back to a delta and again had good SWR. I use a homemade 4:1 duel rod balun at the apex feed point. I am doing a slight foliage adjustment with a Stihl #028 and plan on extending my delta to a 160 size, I will have to make a new 4:1 current balun to lower its center frequency also because the main operation of the loop will be 160 thru 40 and the center point of the balun in use is 10Mhz. I have a hex beam to do the rest, 20 thru 6. The chart below shows how a 283 or a 566 delta loop can cover several bands.

32204. Looks like I was wrong - the Alpha Loop is 10-40M now

Yahoo group: ham-antennas (2014)
Date: 2014-04-28 16:02:14 UTC
From: <aa2nh@...>
Topic: 32204 Message: 32204

Alpha Antenna's loop is now 10-40 Meters (SEE HERE https://amateurradiostore.com/all-alpha-antennas-c-2/new-1040m-microtune-magnetic-loop-antenna-tripod-mount-bag-p-282). So suddenly all my posts about the Alpha Loop only being for 15-40 Meters are incorrect. Fortunately, they haven't tried to break the laws of physics and make their loop work 'as is' on 10-40 Meters continuous. Rather, they still adhere to the rule proven by all Magnetic Loop Antenna calculators, which shows that no MLA should be operated 10-40 Meters without a physical change to the length of the outer loop. In other words, to avoid self-resonance, an MLA should be for either 15-40 Meters or 10-30 Meters, unless you change the length of the outer loop. Constructing a MLA with coverage from 10-40 Meter continuous coverage without changing the physical dimensions of the outer loop is breaking the laws of physics.

From: Alex Netherton
Topic: 10944 Message: 32206

>>If you're looking for a dx antenna for 80m get a vertical. Even if you can only get it vertical for 8m then slope the rest to the ground that works just as well as a vertical. >>

The kicker here is to ground it as well as you can. If you live on the beach or where the ground is saturated with salt water, or perhaps even fresh, then a 4 foot ground rod (8 foot is better, of course) is all that is needed. For the rest of us who live in "ordinary" soil, then ground radials are in order. For 80 meters, four (4) 65 foot radials can make all the difference. If you can do it, bury them an inch or so. If you can't do that, then string a 65 foot piece of wire around the base of the house.

What he is talking about is a "lazy L" antenna, where you get as much of it as possible vertical, and then run the rest out horizontally; it still acts as a vertical.

32207. 40 meter 1/2 wave

Yahoo group: ham-antennas (2014)
Date: 2014-04-28 17:57:05 UTC
From: <rs1946@...>
Topic: 32207 Message: 32207

I have a 40 meter 1/2 wave wire dipole antenna about 18 feet off the ground strung between two short trees. The antenna is feed with about 80 feet of 50 ohm coax. I also wound about 18 feet of coax around a piece of plastic pipe. question is do I need the winding or should I keep the winding but make it shorter. Also I needed to support the plastic pipe and it is taped to a long piece of 3/4 copper pipe going thought the center of the pipe. Does the copper pipe affect the antenna. Thanks Bob

32208. Re: [ham-antennas] 40 meter 1/2 wave

Yahoo group: ham-antennas (2014)

From: Don Sanders
Topic: 32207 Message: 32208

It is probably best to keep the ugly current balun in the line of coax. Hopefully it is close to the antenna. For 40 meters you should have about 20 feet of coax in the winding. The copper pipe should not affect the winding but I get the impression it is not at the feedpoint of the dipole where it should be.

Rich,

Do you have that chart as a Excel document or similar? I'd like to take a look at it. The way you sent it is not formatted as a chart, but as a single column of text.

With all this talk about loops recently, I printed off a Google Maps image of my property just to see what I could possibly string up as far as loops go. I think I can put up a loop that will be approx 90' x 56' x 90' x 50'... mostly a rectangle. The total wire length would be 286', which looks like it will be in the range of 3.6MHz or so... I think I might just add on a few more feet of wire to run down to my SGC-239 auto tuner (coupler) with a few spacers I have - to make an open wire feed - for multiband use. The length of the feed wouldn't be very long at all. I think I could get the antenna up to about 28', but not sure about that. The least expensive fiberglass poles I've seen that are that length are the Jackite poles, which I know are kinda flimsy at the top. I wonder if they would even be able to support 18ga wires of that length.

Anyway, it's nice to know that I can have an 80m loop on my property (I could do larger but that would involve going over/under our electrical service drop... don't want to even go there).

Topic: 6496 Message: 32213

Sorry about the chart before

Subject: RE: AW: [ham-antennas] Re: Loop antenna

Sorry for the first chart I sent

I cannot explain why in a technical form but I know my antenna does not work as a square with good SWR points. Mine is a 80M size delta loop and has low SWR on all but 18 & 10Mhz but my internal tuner takes up the slack on those bands. I lowered my antenna one time because of a ice storm, raised it back up thru about 18” of snow and the readings were off because I had lost a support in a tree. I reset the shape back to a delta and again had good SWR. I use a homemade 4:1 duel rod balun at the apex feed point. I am doing a slight foliage adjustment with a Stihl #028 and plan on extending my delta to a 160 size, I will have to make a new 4:1 current balun to lower its center frequency also because the main operation of the loop will be 160 thru 40 and the center point of the balun in use is 10Mhz. I have a hex beam to do the rest, 20 thru 6. The chart below shows how a 283 or a 566 delta loop can cover several bands.

My limited experience with full size horizontal loops fed with a 4:1 balun has shown me no resonance peaks (VSWR is around 1.5:1 to 2:1 from about half the resonant frequency through HF.) I only receive on the loops. YMMV 73 de dave/kd6il

When did this become forum to tear down the ARRL books and other publications? Lets keep some of this stuff to ourselves if it runs contrary to the majority of operators now on the air. The ARRL and all of it’s publications have been the driving force for Amateur Radio for far longer than most of us have been alive. To start trying to pick apart the manuals serves no purpose. Let’s please stay on topic and be civil in the discussion of antennas. We can agree to disagree on some aspects of antennas and how they operate without all the other.

Jim,

The General Class Amateur Radio License does not expect anyone to know anything.
The license examination itself is nothing more then a primer.
The questions on the test exposes the operator to a smorgasbord of topics and gives you a little exposure to those topics.

The old hams that wrote the test uses this as a way to identify those that are unwilling to study and learn.

The test itself is nothing more then memorization.
A person that has a good memory can identify the questions and pair them up to the right answer and regurgitate the right answer just long enough to get the license.

The antenna book shows you how to build a simple antenna.
Lets take the G5RV for example.
The G5RV is a very poor resonator.
It's creator - Louis Varney took that design to the grave with him, because it bothered him so much that it didn't work especially well - anywhere except 20 meters.

When the G5RV was designed, the transmitters used tubes and the matching networks were very robust..
A Johnson Matchbox is a good example.

Un-knowledgeable hams often times exclaimed that you could tune up everything from a bed bug to the London bridge as long as you used a piece of ladder line..

It was the coaxial cable that caused all the problems for the hams that came along after the golden era of ham radio.

The only thing the antenna book will teach you is how to layout and build a antenna.. The rated gain of the antenna and the lobe angle expected from the antenna at X height.

The take off angle of your signals and the signals you wish to receive is very important.

Everything pertaining to radio is all about Location, Location, Location....

Being in the highest place gives you a great take off angle and offers you the most signal available, but also increases the noise level..

Its not always advantageous to have the highest antenna or live in the highest elevations.

NVIS can be a very good antenna if you do not want to work DX, and just want to listen locally - up to 500 miles - which is what most hams does anyways.

My Elmer once said there are two kinds of antenna's, the kind that works and the kind that does not!

---In ham-antennas@yahoogroups.com, <jim.geidl@...> wrote :

I'm sure this is some kind of heresy but I just have terrible time understanding the ARRL Antenna Book. Can you guys suggest something different that I can read that will help me understand antennas? I know that I am supposed to have a complete understanding of the subject to have a General Class license but that just ain't the case.

Thanks,

Jim, K6JMG

From: Richard Schmuke
Topic: 6496 Message: 32220

Joe, I have a W2AU balun and that is what got me into building my own, I checked it with a carbon resistor and it was so far off on the upper and lower bands that I started to make my own so I would have at least a good start with a low SWR and hopefully less loss.

Rich, Kd0zz

Subject: Re: [ham-antennas] Loop Antennas

Here is an interesting question.

The 4 to 1 balun I do have, (commercial made one) OLD, ohh 5 years maybe? A W2AU made one. Now it is totally weathered, so there is no visible writing anymore.
Is there a way to tell if it is a current,, or a voltage one?

On 4/28/2014 9:48 AM, soona4sail@... wrote:

Loop antennas, are my favorite antenna. I am lucky enough to have enough room to build large loops (in excess of 1000 ft) but even smaller loops (40 mtr and up) work very well.

Couple of points: To get the most out of your loop, and to make it into a multiband antenna, it should be fed with a balanced line. My feedline comes down to a 4 to 1 current balun, just outside the shack window, then

short piece of coax, for convenience, thru the window to a tuner. My Elmer tells me to use a CURRENT balun,and NOT a voltage balun. Voltage baluns, according to him, are a sure fire way to guarantee RF on the outside of any coax in the system.

It is also important to avoid multiples of frequency wavelengths on your feedline. Google "Feedline lengths to avoid"

Finally, here is a link (not me) to one of the best loop antenna construction sites on the internet I have found.

http://www.k5rcd.org/hor%20loop%20instruct.htm

Loop antennas, are simple, inexpensive, and work well. If you can, build your own open wire feedline, it is the best way to go. The twin leads, and open wire ladderlines, have their own set of issues, i.e. sometimes the wires breaks inside the insulation, and they are very

susceptible to tuning issues when wet, frosty, or covered in snow.

Good luck and good DX

Probably close enough since you antenna is so low.
Too bad the antenna has to be low. it would be better
at 30 or more feet high at center and then possibly
inverted vee with 120 or more degrees angle between legs.
In Florida I had no high trees so mine was like mentioned
using 2X4 mast for center. In Alabama had 80 foot pine trees
and the Carolina windom and inverted vee worked well.
Here in Ecuador no high trees but 30 to 40 foot bamboo poles
to hold the fan dipoles work well.

From: <hamuneggs@...>
Topic: 32223 Message: 32223

Had the chance to pick up a 40' tower with base plate and top spire for $150, couldn't pass it up as I've always wanted a tower. Now the big question of the day, does anybody know where I can get plans to build a "robust" beam antenna? I'm afraid some of the "wire" structures other than dipole, probably won't stand up to the wind. We have had gusts up to 120 mph and sustained better than 70 mph at times. We live in the Wet Mountain Valley in Colorado. Great place most of the time, 9000', on top of a hill and no trees to worry about. And the best part no HOA!!!

32227. Fiberglass support mast/pole

Yahoo group: ham-antennas (2014)
Date: 2014-04-29 14:39:24 UTC
From: Geoff NW7GM
Topic: 32227 Message: 32227

Good morning group,

I am in the process of sourcing out some fiberglass support poles for an 80m loop I am considering putting up on my property. I would happily use trees if I had them, but I don't.

I have looked at both the Max Gain (32' @ $119.95) and Spiderbeam (40' @ $119) poles but since I will be purchasing 4 of them, those two poles are a bit out of my price range. I have also looked at the Jackite 31' poles (~$60/ea) which are much closer to my price range but don't seem as robust as the other two. Have any of you had any experience with the Jackite poles? I see on eham that they get great reviews, but I don't see anyone using them for suspending an 80m loop.

Do any of you have any other suggestions for support poles?

Thanks,

Geoff, NW7GM

From: Jim Bennett
Topic: 32227 Message: 32234

Geoff,

I have had a Jackite for about 3-1/2 years. It is a "tool" I could not live without. However, the top section is fairly flimsy, and I doubt it would be strong enough to keep any sort of 80 meter loop suspended without some serious bending, unless you are using some very thin wire, like #26 AWG or thinner.

I'd say that 99% of the time I use the Jackite for erecting / moving my wire antennas around in the trees on our property. I removed the top section and keep it in the garage. I then fashioned a small "hook" out of insulated #10 solid coper wire and duct-taped it to the top of what is now the top section. This hook is what I snag my wires with. The other 1% of my Jackite's use is in supporting a 40-6 meter portable end fed vertical when operating in the back yard or on camping trips.

I have also looked at the Jackite 31' poles (~$60/ea) which are much closer to my price range but don't seem as robust as the other two. Have any of you had any experience with the Jackite poles? I see on eham that they get great reviews, but I don't see anyone using them for suspending an 80m loop.

From: Billy McFarland
Topic: 32227 Message: 32235

I used a portable delta loop and for a vertical antenna. With a 10m pole and the top section removed I glued in an m4 but so that I could screw a clip into the end to hold a wire. I mainly use auto car wire. Which is 16 awg but I have used 14 awg with my portable loop. Yes they do bend but supported at the bottom enough and allow for the bending it should take your wire no problem. Murmur will not take a weight of the balun at the top but from 1m of the ground the balun if used could be placed there.

Thanks Billy. I was planning on using 18ga wire, but I'm sure that 16ga would be sufficient as well since I will only be running 100w max. I'm not planning on using a balun as I have an SGC-239 that I will be using to feed either some window line (450ohm) or I'll just extend the wires of the loop a bit longer to create an open wire feed with some spacers I have. I haven't decided that aspect yet.

Do you have a particular brand of pole you're using?

From: James M. Geidl
Topic: 32227 Message: 32237

This is almost exactly the same use I have for the Jackite, although, I am about ready to try it with some 27 guage braided wire I have to make a temporary long wire antenna to use with our motor home. I will put the Jackkite on the back of the RV and run the wire out a couple hundred feet to a tree or post or, maybe, another Jackite.. I can use some more of the wire to make a temporary counterpoise. I am going to put the wire on a fishing reel for easy of deplayment and retrrieval. This is a TEMPORARY setup while in a RV park as I don't think the Jackkite will standup to having the set in any kind of a permanent way.

As Jim said, it makes a great tool.

James "Jim" M. Geidl, K6JMG

If I were to use 20, 22, 24 or even 26ga wire, what kind of power handling would they have? As I said, I will be running 100w MAX. Most often though it will be less as I do quite a bit of digital work.

I got mine from eBay around £23 per pole. These were another name made by Diawa. Haven't had a problem with them although some pole can go to £120 I don't see the point in paying a lot of expense if they are going to get damaged by hard winds or whatever it will happen with an expensive one as well. That's what I've certainly found

I have #26 AWG on my 88 foot long doublet and have been running up to 500 watts with no problem. I feed it with 450-ohm ladder line.

At 100 watts as long as the wind does not break it you are OK. 26 gage is not very strong in tensile strength for a long loop. Pulling on the wire to keep if from having too much sag on it will over load 26ga doing a loop. My antenna book says a 20ga wire should have a max load on the end of 5 lbs(20ga is as light as it goes). Looking at it from the other side of the fence 12 or 14ga will be too heavy for fishing pole supports. 26ga wire is only .016 diameter , 24ga is .020. ,22ga is .025, 20ga is .032 or twice the diameter of 26ga. Also use bare wire for less weight and wind load if you are going very light. What sizes do you have on hand??

If I were to use 20, 22, 24 or even 26ga wire, what kind of power handling would they have? As I said, I will be running 100w MAX. Most often though it will be less as I do quite a bit of digital work.

> they have?

I don't know the exact answer to your question. I am certain it would depend on many factors, the LEAST of which would be the amount of power you connect to it.

However, I can give you an interesting anecdotal report from my own experience.

Back in the 1960s, I attended College at Montana State College in Bozeman, Montana studying Math-Physics, and I lived in a three-story dormitory building with the other students.

One of the students, a ham radio op, and an electrical engineering student, had been given a WWII BC-610 transmitter which didn't work.

Output power of the BC-610 is rated at 300 watts on CW, although it can be easily loaded to more than that. The final amp tube is a 250TH which has a plate dissipation rating of 250 watts.

Although having an operating ham radio in the dorms was forbidden, we cajoled a janitor in taking this 400 lb rig up to the second floor dorm room of the owner in the freight elevator one night.

After some troubleshooting, which included clearing a dead short in the HV (2800 VDC) power supply during which we blew the main breaker for the entire dorm, we got it working very well.

Since antennas of any kind were likewise forbidden, for our antenna, we used #36 black enameled solid wire. We ran a piece of this stuff, exactly 66 feet long, from one dorm window to a window in an adjacent dorm, using small rods of polystyrene as insulators. From a distance of 5 feet one couldn't even see it against the sky even if you knew it was there.

I have forgotten what we used for a receiver, but over that semester, we worked a lot of DX on the 80, 40, and 20 meter CW bands with the setup.

The owner took the complete setup back to his home when the semester ended.

The only problem we had with the #36 black enameled wire antenna was when, one morning, we woke up early to find it coated almost 1 inch thick with frost, making it extremely visible. We simply snapped our end of it, letting it fall, then put it back up that night.

So, in our case at least, 300 watts to a 66' long end fed wire made of #36 black enameled wire worked very well.

YMMV ;-)

I am using a OCFD made up of 22 gaqe stranded wire [7 strands] .

I have put out about 1000 watts [HL2200] on this antenna [80,40,20 meters, ladderline, antenna tuner] with no adverse effects noted . I get reasonable to good reports at 100 watts and good to very strong reports at 1000 watts .

Best in your project.

We used al fence wire several times on field-day cause it is SOOOO light-weight (and also cheap!)

On a warm and sunny day it is nearly bending upwards (just kidding a bit)

Even on VERY long runs it does not need much tension to have a low sag

And you can pull very hard on it when needed

500 feet or more with just two trees at the ends?? No problem!

Most of installations we made there the insulators and support ropes made more weight as the wire itself ...

Connecting a dipole or loop to ladderline?!? We used stainless steel hardware (screws, nuts and whasers) .... and cause it was just for a few days there was no problem caused from the dissimilar metals

Hope that helps a bit

Dg9bfc

Sigi

Ps there IS special flux and solder available for al ... so even that could be solved when needed

Rich,

This isn't Litz wire, it is braided wire that I am assuming was used for jewelry. It looks like it is about 7 strands. I stumbled across it at a garage sale. BTW, it is clear plastic coated. I have not tested it for strength but am betting it will carry it's own weight out to 200 feet or more with little effort.

James "Jim" M. Geidl, K6JMG

I am in the process of sourcing out some fiberglass support poles for an 80m loop I am considering putting up on my property. I would happily use trees if I had them, but I don't.

I have looked at both the Max Gain (32' @ $119.95) and Spiderbeam (40' @ $119) poles but since I will be purchasing 4 of them, those two poles are a bit out of my price range. I have also looked at the Jackite 31' poles (~$60/ea) which are much closer to my price range but don't seem as robust as the other two. Have any of you had any experience with the Jackite poles? I see on eham that they get great reviews, but I don't see anyone using them for suspending an 80m loop.

Do any of you have any other suggestions for support poles?

Thanks,

Geoff, NW7GM
Seattle, WA

Jim,

just so I understand when you say braided do you mean litz wire or stranded? I have often wondered if litz would be worth the extra cost. It would make a nice portable setup when you put it away.

Subject: Re: [ham-antennas] Fiberglass support mast/pole

Geoff,

I have had a Jackite for about 3-1/2 years. It is a "tool" I could not live without. However, the top section is fairly flimsy, and I doubt it would be strong enough to keep any sort of 80 meter loop suspended without some serious bending, unless you are using some very thin wire, like #26 AWG or thinner.

I'd say that 99% of the time I use the Jackite for erecting / moving my wire antennas around in the trees on our property. I removed the top section and keep it in the garage. I then fashioned a small "hook" out of insulated #10 solid coper wire and duct-taped it to the top of what is now the top section. This hook is what I snag my wires with. The other 1% of my Jackite's use is in supporting a 40-6 meter portable end fed vertical when operating in the back yard or on camping trips.

What would be the shortest run suggested for transitioning from the loop to the feeder? In my application (depending on where I place the tuner) it could be either 8' or 25'.

32254. AW: [ham-antennas] Fiberglass support mast/pole

Yahoo group: ham-antennas (2014)
Date: 2014-04-29 22:34:55 UTC
From: siegfried jackstien
Topic: 32227 Message: 32254

It does not matter much ... but could influence tuning on some of the higher bands (if used multiband) ...

Make it longer and try it out would be my best suggestion

I would need some more details (length of loop, bands used, length of feeding-line)... and then how you wanna feed that (used tuner ... added balun or not) ...

But my overall thinking is ... build it and you will love it :-)

From: Richard Schmuke
Topic: 32227 Message: 32255

Wont solder, braided, non magnetic , 27 gage ?? Sounds like stainless from here. FYI, a side note from the Kd0zz work shop, I solder stainless steel all the time with Oatey flux , #30106, not for circuit boards but fine for antenna work. The best is Ruby brand but it is 16 oz and Oatey is 4 oz. Just clean the joint after soldering.

Rich, kd0zz

From: Richard Solomon
Topic: 32256 Message: 32256

I have one of the 50' MGS Fiber-Glass poles and wonder how folks anchor it at ground level.

I thought just a piece of pipe beat into the ground might do. there will be sufficient guy ropes to hold it up, I just don't want the bottom moving around.

Anything more sophisticated one might suggest ??

Thanks, Dick, W1KSZ

For our field-day pole (aluminium push up pole) we have a thicker piece of wood with a hole inside

Can be "nailed" to ground with 2 thicker "staples"

Easy, cheap ... and works well

The total wire length of the horizontal loop will be in the order of 286 feet. I'll be using RG8 to my SGC-239 autotuner that will be connected directly at the feed of the antenna - no balun. I'm thinking this will be an 80 - 10m (maybe even 6m?) loop.

I'm thinking the wire choice will be somewhere between 20-24ga but I haven't made a definite choice yet.

32260. Re: MGS Push-Up Pole Ground Mount

Yahoo group: ham-antennas (2014)
Date: 2014-04-30 02:13:09 UTC
From: <w6jhb@...>
Topic: 32256 Message: 32260

Interesting to get this email today - I just built a bottom support system this afternoon, although my fiberglass poles are from DX Engineering. I dug a 12 inch hole in the ground, placed a 12 inch long1-1/2 inch pipe in it and filled it with concrete. One bag did the trick. Into that pipe I slid a 24 inch long 1-1/4 inch pipe, and my bottom fiberglass pole sits on it / over it. I did not go up 50 feet. More like 25, but my pole will be holding a 12 meter Moxon beam and I didn't need the height or to annoy the neighbors.

Jim / W6JHB

From: siegfried jackstien
Topic: 32227 Message: 32262

So you wanna feed a loop (balanced amtenna) ... with the scg tuner (unbalanced tuner) ... ?!?

I would then let the tuner "float" (rf-wise) ... means I would add a balun (choke) on the input side of the tuner ... and also a choke in the power lines for the tuner ... that takes care of that only the antenna radiates (no common mode current on the coax shield or power lines)...

You can try it out without a balun ... but I would recommend to use one

You also can add a balun on the output side of the tuner ... (like it is done in dozens of manual tuners)

In my yaesu fc1000 autotuner (nearly the same thing as your sgc tuner) I had some "spare" room ... and I added a 1:4 there

Now if needed I can connect the output (or the tuner) to the balun and then connect the (balanced) antenna there ... or use the tuner without balun (longwire or whip antenna)

Try out what works best

If the tuner does not find a match on a given band ... then change the setup and try again ...

Sure you will find one solution that works on all bands (10-80)

If you can add a bigger number of radials below the antenna you also can connect both ladderline wires together and use the ladderline and the loop as a "vertical with a big topload" ... (you sure know what I mean)

For that you had to place the tuner at the ground ... otherwise you can mount it on a pole in one of the loop-corners (I would use the first setup! on the ground) ...

Cause ladderline has nearly no loss you can play around with lengths of loop and ladderline till you find a setup that works on all bands (except topband ... there an 80m loop does not work)

Good luck

AFAIK the SGC is a balanced tuner. The output is two screw terminals, not an so-239. It is very much like the SG-237 or SG-230, just without the waterproof case (I have mine in a CATV demarc box).

The choke @ the input if the tuner is a good idea and I was planning on that part already (on both rf input and control line).

I'll think about your other suggestions as well.

Thanks,

Geoff, NW7GM

A balanced tuner just cause it has 2 screw terminals?!? That is a VERY ROUGH GUESS :-)

Does the tuner has a balun on the input??

Are all tuning parts (coils and caps) TWICE in the tuner (real balanced)??

I think that tuner is an actual proper balanced tuner rather than using a balun inside it.

You're right, it is just a guess - one that is based on the manual as there are several 'suggested antenna configurations'. Included are loops and dipoles (fed with balanced line). Here is the manual for the tuner:

http://sgcworld.com/Publications/Manuals/239man.pdf

There's a schematic in there so you can see what is included in the tuning parts.

Chuck, Whatever info you have on your loop, please send to me. If you have a 4NEC2 model, by all means send that to me.

In fact if anyone has a 4NEC2 model for a loop, please send to me.

OH - I meant to say 40M - 7 MHz,. sorry.

Tks,
Joel - N3GSE

Kind-a-scary, says 80 Watts in one place and 200 Watts in another.
The component layout is marked in two places "RF HOT" and "RF ground"
which screams not a balanced tuner. The RF path through it is single sided.

The manual on page 32 states

5. The SG-239 can be used next to your transceiver as a RF line feed
trimmer for balanced or unbalanced lines of 100-
1000 ohms or coaxial lines (25-100 ohms). The unit does not require a
balanced transformer to perform efficiently.

So no need for a balun or unun.

Another source of mast are used fibreglass windsurfer masts - 12 to 16 ft. Goood for wires but I wouldn't attempt anything bigger than a 6m dipole on top.

What about making your own out of PVC? I've talked to hams in New Hampshire and he's made himself a mast out of it. Made a small base and guide it for QRP/portable work. I do believe he got the idea out of a QST ad. I can't remember who has them. But made them larger than what the ad ha for some stiffness. Height was about 20ft/7meters high.

I've also thought about making one myself for portable operations and making a larger base and larger diameter PVC for a longer dipole for when I'm camping.
I have the diagram drawn in my "home-brew wish list" notebook. It's small enough (2 1/2in... 6.3cm) at the base to 1 1/2 in/ 3.8cm at the top. Only about 10ft/3.5 meters overall height... Also thought about using wood to stiffen the vertical part in certain parts.

Overall cost would be $20-$40. I've also check at my local commercial store(Lowes/Home Depot) if they had some precut pieces(scrap) and they sell them for a few dollars.

I have this antenna. It is also at 200". With the stub the way it came out of the box. Never measured the stub. Once in the air I just rotated the ring adjustment until I got a 1:3/1 swr at 28.400. It stays that way from 28.200 -28.600. Wish I had some Ideas but it does work if you can get it tuned.

Good Luck

I'll tell you what I found when I considered building a mast from PVC.

I got the idea of using decreasing sizes of PVC from a book published in 1988.

When I looked at PVC from Lowes and Home Depot, it appears not everything is solid PVC.

The larger sizes, beginning at 1 ¼", marked DWV, may be a foam core with a PVC cover, not solid PVC.

Make sure to inspect and verify that it is solid PVC before buying.

Putting wood inside the PVC insures it won't eventually bend in hot weather. I've used this method in the Philippines.

Dave Tadlock KG0ZZ has a you tube channel where he used a wooden closet rod to stiffen up a shortened dipole. He used PVC as the support. This is how I got the idea. Yes it might effect the antenna a little. But shouldn't be much...

DWV = "Drain, Waste and Vent", i.e. pipe not rated for any pressure or heat.

The stronger (and more expensive) stuff is rated (in the US) according to "schedules", Sched 10, 20, 40, 80 are what I've heard of (for PVC), getting progressively stronger with increasing number. These are the same numbers as used for steel pipe. Supposedly Sched 40 PVC pipe, say, has the same dimensions (not the same strength) as Sched 40 steel pipe.

But yeah, DWV pipe is as weak as a kitten.

The DWV that Lowes sells is also marked SCH 40.

To further complicate the issue, solid PVC pipe is dual marked DWV.

Hence, my comment to inspect to be sure what you're buying.

DWV = "Drain, Waste and Vent", i.e. pipe not rated for any pressure or heat.

The stronger (and more expensive) stuff is rated (in the US) according to "schedules", Sched 10, 20, 40, 80 are what I've heard of (for PVC), getting progressively stronger with increasing number. These are the same numbers as used for steel pipe. Supposedly Sched 40 PVC pipe, say, has the same dimensions (not the same strength) as Sched 40 steel pipe.

But yeah, DWV pipe is as weak as a kitten.

It will work without a balun ... but it will work BETTER with a balun added

Equal currents on the ladderline (or on both legs of dipole/loop) ... and NO CURRENT ON OUTSIDE OF COAX!!! ... no common mode current ... no "hot lips" on the microphone ... no rf in the shack

The tuner will work ... but it is not a balanced device

That tuning stup is needed!! ...

The "slider" is adjusted for 50 ohms impedance ... and length of antenna
sets the resonance point higher if you make it shorter

So look carefully how you assembled the antenna ... maybe you made a fault
with connecting the ring and the slider?!?

OK FOLKS:

Here are the rules of the reflector : HAM-ANTENNAS
This file will be sent once a month automatically to remind all users.

1. Name calling (race, religion, politics, gender, etc.), is prohibited.
2. Telling someone they are ignorant (in any way, shape, or form), is prohibited.
3. Denigrating other races or minorities, or expressing POLITICAL VIEWS will earn you moderation or banning.
4. If you do it privately it is a private dispute. When/if it spills over onto the reflector, you will be moderated or banned.
5. Even coming close to these boundaries is to be avoided.
6. Banning/moderation will be used, with NO notification to the transgressor.
7. Civil chatter and Civil wordage is THE rule.
8. IF the Moderators are offended, then penalties will be applied.
9. There are two Moderators, EITHER can ban/moderate you.
10. Moderators ARE the final arbitrator of disputes, we hate bickering!
11. USE Private or Direct Emails to address your concerns to the Moderators, because public postings may likely result in penalties as above. !!!!
12. Use common sense. If you would be hurt or upset if you received what you are about to send, and you are intentionally meaning to do that, DON'T DO IT!

13. We ALL would like to enjoy discussion about HAM-ANTENNAS, nothing more.

32287. New Antenna Measurement Question

Yahoo group: ham-antennas (2014)
Date: 2014-05-01 17:19:09 UTC
From: Jim Bennett
Topic: 32287 Message: 32287

Hi Folks,

Looking for an answer to a minor issue I've run across. I just completed building a Moxon Rectangle beam for 12 meters, per the data at the web site of KG4JJH.COM. It is mounted atop an 18 foot tall, guyed fiberglass mast in the middle of the back yard. For my initial testing, I had hooked a 50 foot length of DX Engineering RG-8X to the beam. Sitting on the back patio, I connected the free end of the coax to my AIM-4170C analyzer. I was pleasantly surprised to see impedance to be between 50-46 ohms across the entire 12 meter band. The SWR showed up at 1.25:1 at the bottom of the band and increased only to 1.4:1 at the top. Sweet, I thought.

I prepared a sufficiently long length of the same type of cable to run from the beam over to the shack, somewhere in the vicinity of 90+- or so feet away. Since I have several antennas here (don't tell the CC&R/HOA police!) I run all my cables into an MFJ 4603 Window Pass-thru Panel. On the inside of the panel I ran a six foot length of that same coax and connected it to the AIM-4170C, just to verify my readings from yesterday afternoon. They are OK, but not what I had expected. Now, I am seeing the Impedance as still flat, but at about 75 ohms. My SWR had also gone up a tad; it is now about 1.6: across the entire band. At first I thought my six foot length of inside coax was to blame, so I replaced it with another piece, about 20 feet long. No real change - still higher impedance and SWR. Tried a different "port" on the MFJ pass-thru. No change. I have a four foot length of #4 copper wire running to a five foot long copper clad steel ground rod. Tried disconnecting that from the MFJ. No change. I put the six foot piece back in place and went outside with the AIM-4170C, disconnected the 90 foot length of coax from the MFJ pass-thru and connected it directly to the analyzer. My readings were fairly consistent with what I got yesterday on the patio.

So, I'm pretty confident that this variance in SWR and impedance is due to it being connected to the MFJ pass-thru, but why? This thing is constructed such that all coax cables connected to it have their outer conductor in common - it is an aluminum plate sandwiched between a wood frame. This is the only thing I can think of, but then again, all my equipment is tied together with a ground cable, so what's going on here?

32289. How to Minimize Antenna Sway.

Yahoo group: ham-antennas (2014)
Date: 2014-05-01 19:00:28 UTC
From: <worahm@...>
Topic: 32289 Message: 32289

I just sold my Suburban which freed my Kenwood 7950 for base station use.

I purchased a SlimJim Jpole antenna fabricated from copper tubing, that I intend to hang from a 40 foot high tree limb with wx resistant cord just inside the wood line behind my house. The slim jim is about 5 feet tall.

At this point, I know that the wind moves the trees so I am guessing the antenna will also sway. However, I am not certain what effect a swaying antenna will have on my signal. I have been told it could be detrimental. In any case, I am thinking it would probably be a good idea to do something to minimize the sway

I am considering tying 3 or 4 small diameter cords from the bottom of the antenna to 3 or 4 surrounding tree trunks.

I am open to any and all solutions. Maybe a couple of little muffin fans set up to counter the effects of the wind would do the trick.

Yep, I can probably resolve this issue by not using that MFJ pass-thru. And now I'm wondering if it has had the same effect on my other antennas and I've not noticed it before...? Hmmmm....

Anyway, doing away with it is easier said than done. I have six coax lines, a station ground, and a 14VDC solar panel positive and negative power cable to account for. Whatever would replace the MFJ 4603 would need to be non-conductive AND relatively thin, which kinda limits what I can use. Suggestions?

Jim,

Sounds to me like you have some CMC flowing and the coupling of the shields of the other antennas is causing a change in the end feed point impedance. I suggest you just disconnect the pass thru and couple the antenna directly to the radio/analyser and see if the measurement is the same. If so, isolate the shield of the Moxon from the rest of the pass thru.

Mel, K6KBE

A little sway won't hurt the slim jim. Mine hangs from a 20' pole in back of my apartment. (One of the n9tax antennas)... performs very well, with simplex reaching out almost 40 miles. I'd LIKE to push it up another 10 feet, but a fiberglass pole bends a bit, and with the wind around here, I don't think it would stay put. (It would join the ground..)

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

Scott there isn't anything special about the MFJ pass-through, it is
basically what you describe.
I don't know what could be causing Jim's issue though.

Jim how old is the MFJ pass-through?

32294. Re: [ham-antennas] New Antenna Measurement Question

Yahoo group: ham-antennas (2014)
Date: 2014-05-01 19:36:47 UTC
From: Jim Bennett
Topic: 32287 Message: 32294

Hi Mel,

I did that - I connected the AIM at the outside of the house, directly to the feed line of the Moxon without going thru the pass-thru, and the SWR & Impedance went back to where they were yesterday. So, it is the MFJ pass-thru causing the change. It wouldn't break my heart to replace the MFJ with something else, but as I noted in my last post, with what? :-)

What about making your own? Prolly would be cheaper than buying another commercial made pass thru. That's what I've done. Well, one for the car window. And I'm going to be making one for the apartment window. A little paint, to seal the wood and blend it into the window casing...

So when you connect it thru the pass thru the swr goes bad??

Did you try a different connector in the panel??? Maybe one of them is bad only (and can replaced with a good one)

Yes, I tried a different connector - still not so good. Not real bad, but not the same as when no pass-thru is involved.

Jim, 6MM thick polycarbonate (Lexan), shatter proof window replacement from the hardware store. It is easy to cut , drill and whatever. A couple of strips into the window , overlap the center and RTV together, some RTV on the edge, bulkhead fittings or thru the strip and RTV. Insulators for ladder line, ground wire , whatever you want.

http://i1102.photobucket.com/albums/g453/KD0ZZ/PassThru.jpg

No snide remarks about the curtain are required. Leftover polycarbonate scraps make good dipole centers.

http://i1102.photobucket.com/albums/g453/KD0ZZ/QuickChangeDipole008.jpg

Or equipment racks

Yep, I can probably resolve this issue by not using that MFJ pass-thru. And now I'm wondering if it has had the same effect on my other antennas and I've not noticed it before...? Hmmmm....

Anyway, doing away with it is easier said than done. I have six coax lines, a station ground, and a 14VDC solar panel positive and negative power cable to account for. Whatever would replace the MFJ 4603 would need to be non-conductive AND relatively thin, which kinda limits what I can use. Suggestions?

Subject: [ham-antennas] New Antenna Measurement Question

Hi Folks,

Looking for an answer to a minor issue I've run across. I just completed building a Moxon Rectangle beam for 12 meters, per the data at the web site of KG4JJH.COM. It is mounted atop an 18 foot tall, guyed fiberglass mast in the middle of the back yard. For my initial testing, I had hooked a 50 foot length of DX Engineering RG-8X to the beam. Sitting on the back patio, I connected the free end of the coax to my AIM-4170C analyzer. I was pleasantly surprised to see impedance to be between 50-46 ohms across the entire 12 meter band. The SWR showed up at 1.25:1 at the bottom of the band and increased only to 1.4:1 at the top. Sweet, I thought.

I prepared a sufficiently long length of the same type of cable to run from the beam over to the shack, somewhere in the vicinity of 90+- or so feet away. Since I have several antennas here (don't tell the CC&R/HOA police!) I run all my cables into an MFJ 4603 Window Pass-thru Panel. On the inside of the panel I ran a six foot length of that same coax and connected it to the AIM-4170C, just to verify my readings from yesterday afternoon. They are OK, but not what I had expected. Now, I am seeing the Impedance as still flat, but at about 75 ohms. My SWR had also gone up a tad; it is now about 1.6: across the entire band. At first I thought my six foot length of inside coax was to blame, so I replaced it with another piece, about 20 feet long. No real change - still higher impedance and SWR. Tried a different "port" on the MFJ pass-thru. No change. I have a four foot length of #4 copper wire running to a five foot long copper clad steel ground rod. Tried disconnecting that from the MFJ. No change. I put the six foot piece back in place and went outside with the AIM-4170C, disconnected the 90 foot length of coax from the MFJ pass-thru and connected it directly to the analyzer. My readings were fairly consistent with what I got yesterday on the patio.

So, I'm pretty confident that this variance in SWR and impedance is due to it being connected to the MFJ pass-thru, but why? This thing is constructed such that all coax cables connected to it have their outer conductor in common - it is an aluminum plate sandwiched between a wood frame. This is the only thing I can think of, but then again, all my equipment is tied together with a ground cable, so what's going on here?

Question:

Have you disconnected everything else - inside, outside, the ground connection included, except the Moxon's cables, from the panel and then re-checked the Moxon's SWR?

If the readings go back to the better value, the panel's pass-through connectors are not at fault. You've got some weird common mode stuff going on here.

Subject: Re: [ham-antennas] New Antenna Measurement Question

Hi Mel,

I did that - I connected the AIM at the outside of the house, directly to the feed line of the Moxon without going thru the pass-thru, and the SWR & Impedance went back to where they were yesterday. So, it is the MFJ pass-thru causing the change. It wouldn't break my heart to replace the MFJ with something else, but as I noted in my last post, with what? :-)

On Thursday, May 1, 2014, at Thursday, 12:31 PM, Mel Farrer wrote:

Jim,

Sounds to me like you have some CMC flowing and the coupling of the shields of the other antennas is causing a change in the end feed point impedance. I suggest you just disconnect the pass thru and couple the antenna directly to the radio/analyser and see if the measurement is the same. If so, isolate the shield of the Moxon from the rest of the pass thru.

Subject: [ham-antennas] New Antenna Measurement Question

Hi Folks,

Looking for an answer to a minor issue I've run across. I just completed building a Moxon Rectangle beam for 12 meters, per the data at the web site of KG4JJH.COM. It is mounted atop an 18 foot tall, guyed fiberglass mast in the middle of the back yard. For my initial testing, I had hooked a 50 foot length of DX Engineering RG-8X to the beam. Sitting on the back patio, I connected the free end of the coax to my AIM-4170C analyzer. I was pleasantly surprised to see impedance to be between 50-46 ohms across the entire 12 meter band. The SWR showed up at 1.25:1 at the bottom of the band and increased only to 1.4:1 at the top. Sweet, I thought.

I prepared a sufficiently long length of the same type of cable to run from the beam over to the shack, somewhere in the vicinity of 90+- or so feet away. Since I have several antennas here (don't tell the CC&R/HOA police!) I run all my cables into an MFJ 4603 Window Pass-thru Panel. On the inside of the panel I ran a six foot length of that same coax and connected it to the AIM-4170C, just to verify my readings from yesterday afternoon. They are OK, but not what I had expected. Now, I am seeing the Impedance as still flat, but at about 75 ohms. My SWR had also gone up a tad; it is now about 1.6: across the entire band. At first I thought my six foot length of inside coax was to blame, so I replaced it with another piece, about 20 feet long. No real change - still higher impedance and SWR. Tried a different "port" on the MFJ pass-thru. No change. I have a four foot length of #4 copper wire running to a five foot long copper clad steel ground rod. Tried disconnecting that from the MFJ. No change. I put the six foot piece back in place and went outside with the AIM-4170C, disconnected the 90 foot length of coax from the MFJ pass-thru and connected it directly to the analyzer. My readings were fairly consistent with what I got yesterday on the patio.

So, I'm pretty confident that this variance in SWR and impedance is due to it being connected to the MFJ pass-thru, but why? This thing is constructed such that all coax cables connected to it have their outer conductor in common - it is an aluminum plate sandwiched between a wood frame. This is the only thing I can think of, but then again, all my equipment is tied together with a ground cable, so what's going on here?

It is obvious, when you connect to the panel the outer conductor now
connected to other antennas coaxes adds the other feed lines and
antennas to this antenna system. A balun just before the panel or at the
antenna fed point will help.

It's SO easy to make your own pass thru. I just copied the MFJ and added two more SO239 ports with parts from eBay and Home Depot. Cost was very minimal.

Best regards - Bry Carling

It is mounted atop an 18 foot tall, guyed fiberglass mast in the middle of the back yard. For my initial testing, I had hooked a 50 foot length of DX Engineering RG-8X to the beam. Sitting on the back patio, I connected the free end of the coax to my AIM-4170C analyzer. I was pleasantly surprised to see impedance to be between 50-46 ohms across the entire 12 meter band. The SWR showed up at 1.25:1 at the bottom of the band and increased only to 1.4:1 at the top. Sweet, I thought.
>>>
>>> I prepared a sufficiently long length of the same type of cable to run from the beam over to the shack, somewhere in the vicinity of 90+- or so feet away. Since I have several antennas here (don't tell the CC&R/HOA police!) I run all my cables into an MFJ 4603 Window Pass-thru Panel. On the inside of the panel I ran a six foot length of that same coax and connected it to the AIM-4170C, just to verify my readings from yesterday afternoon. They are OK, but not what I had expected. Now, I am seeing the Impedance as still flat, but at

about 75 ohms. My SWR had also gone up a tad; it is now about 1.6: across the entire band. At first I thought my six foot length of inside coax was to blame, so I replaced it with another piece, about 20 feet long. No real change - still higher impedance and SWR. Tried a different "port" on the MFJ pass-thru. No change. I have a four foot length of #4 copper wire running to a five foot long copper clad steel ground rod. Tried disconnecting that from the MFJ. No change. I put the six foot piece back in place and went outside with the AIM-4170C, disconnected the 90 foot length of coax from the MFJ pass-thru and connected it directly to the analyzer. My readings were fairly consistent with what I got yesterday on the patio.
>>>
>>> So, I'm pretty confident that this variance in SWR and impedance is due to it being connected to the MFJ pass-thru, but why? This thing is constructed such that all coax cables connected to it have their outer conductor in common - it is an aluminum plate sandwiched between a wood frame. This is the only thing I can think of, but then again, all my equipment is tied together with a ground cable, so what's going on here?

From: <k9jfk@...>
Topic: 32289 Message: 32304

Hi Bill,

I wouldn't worry about it. The antenna would need a heck of sway angle to disrupt the signal at the repeater. If signal disruption proves to be a problem, then drop a rope straight to the ground and fasten it to a brick or pipe.

I've had all sorts of 2m antennas mounted outside, including a 16ft tall dual band fiberglass colinear that bent a lot in storm winds. Signal disruption was never an issue.

As my "Pappy" used to say, "If it ain't broke, don't "fix" it!

73, Jimmie, K9JFK

---In ham-antennas@yahoogroups.com, <worahm@...> wrote :

I just sold my Suburban which freed my Kenwood 7950 for base station use.

I purchased a SlimJim Jpole antenna fabricated from copper tubing, that I intend to hang from a 40 foot high tree limb with wx resistant cord just inside the wood line behind my house. The slim jim is about 5 feet tall.

At this point, I know that the wind moves the trees so I am guessing the antenna will also sway. However, I am not certain what effect a swaying antenna will have on my signal. I have been told it could be detrimental. In any case, I am thinking it would probably be a good idea to do something to minimize the sway

I am considering tying 3 or 4 small diameter cords from the bottom of the antenna to 3 or 4 surrounding tree trunks.

I am open to any and all solutions. Maybe a couple of little muffin fans set up to counter the effects of the wind would do the trick.

OK, there are several solutions. First one is that since you see the problem with the pass thru, you can do one of the following.
1. Get a hole saw and punch a larger hole in the panel and cover the hole with a piece of insulation material/plastic from TAP/MASONITE, I don't like it but works if out of the weather. Then punch a hole in the insulation material the same size of the pass thru connector and you are done.
2. Make a new pass through panel as suggested. If you need to do this, you make the panel the size you want, you punch the number of insulated holes you want for either the coax sans the connector or for the pass thru connectors. I did several in the past and when I finished the panel with the cable holes, I cut the panel splitting the panel into two pieces across the centerline of the cable holes, use a thin band saw blade. The two pieces now can capture the cable without the need of the pass thru connector. This is my method of choice.

Good luck in which ever method you use.

Another quick idea to replace your metal plate... McMaster-Carr (and others) sell fiberglass sheet material. If you bought a 2'x3' sheet of 3/16" thick G10 you could cut it to size and install all the jacks you need. This stuff is very strong, stiff, resists water uptake, is flame retardant and is UV resistant. It takes paint well if you tough up the surface. We in the boomerang building community love this stuff.

Hi Jim,

Connecting the braid shields of multiple antennas at a termination point will result in interplay of whatever common mode current is flowing on the feedlines. This is very common and generally will not result in VSWR outside of what your rig can handle. There will always be some shift due to the interplay because your various feedlines also function as antennas and pick up some CMC after the balun (assuming a balun at the antenna end), and closely placed antennas "see" each other and tend to function as one large array creating further complications with tuning.

If you are getting a dramatic swing, take your multimeter and start doing voltage checks between your various antenna feedlines and you will find one or more that are passing CMC and creating the interplay that allows your passthrough plate to function as an inductor.

Contributors are feedlines cut to resonant frequencies, or more commonly in restricted space one or more antennas located too close to each other, or simply the balun or baluns themselves.

The best solution is to not worry about it in an installation like you describe, but use a good tuner at the rig end. There is a very good explanation of CMC and the impacts of VSWR here: http://www.hamuniverse.com/wc7iswr.html http://www.hamuniverse.com/wc7iswr.html It is not the bugaboo that many believe it to be.

Your antenna is not high enough, to be efficient on 10 / 12 meters, it needs to be somewhere in the neighborhood of about 36 or more feet off the ground. 30' would be a minimum in my opinion.

If you look at the specifications - velocity factor for the cable and figure out half wavelengths - you will come up with a length where you should see 50 ohms into a 50 ohm dummy load.

Did you check it with a dummy load?

If you were transmitting and someone walked near the feed line with a florescent bulb, once every wavelength, the bulb would illuminate.
This would be where the E and the H fields meets.

My guess is that you were tricking your SWR meter and analyzer into reading what you wanted it to read.
50 ohm / 75 ohm - who cares.

Tell me the voltage / amperage on the line at the end of the line and the feed point, that is all that I care about.

Raise the antenna, move the antenna into a free space - something in the neighborhood is interfering with it.

Use a resonant half wave length piece of coax when you do your next analysis of the antenna..

In theory, if the antenna is purely resistive - 50 ohms, the length of the coax will not change it's efficiency - not one iota.

Rule of thumb - don't sweat the petty stuff and don't pet the sweaty stuff..

Hi Folks,

Looking for an answer to a minor issue I've run across. I just completed building a Moxon Rectangle beam for 12 meters, per the data at the web site of KG4JJH.COM. It is mounted atop an 18 foot tall, guyed fiberglass mast in the middle of the back yard. For my initial testing, I had hooked a 50 foot length of DX Engineering RG-8X to the beam. Sitting on the back patio, I connected the free end of the coax to my AIM-4170C analyzer. I was pleasantly surprised to see impedance to be between 50-46 ohms across the entire 12 meter band. The SWR showed up at 1.25:1 at the bottom of the band and increased only to 1.4:1 at the top. Sweet, I thought.

I prepared a sufficiently long length of the same type of cable to run from the beam over to the shack, somewhere in the vicinity of 90+- or so feet away. Since I have several antennas here (don't tell the CC&R/HOA police!) I run all my cables into an MFJ 4603 Window

Pass-thru Panel. On the inside of the panel I ran a six foot length of that same coax and connected it to the AIM-4170C, just to verify my readings from yesterday afternoon. They are OK, but not what I had expected. Now, I am seeing the Impedance as still flat, but at about 75 ohms. My SWR had also gone up a tad; it is now about 1.6: across the entire band. At first I thought my six foot length of inside coax was to blame, so I replaced it with another piece, about 20 feet long. No real change - still higher impedance and SWR. Tried a different "port" on the MFJ pass-thru. No change. I have a four foot length of #4 copper wire running to a five foot long copper clad steel ground rod. Tried disconnecting that from the MFJ. No change. I put the six foot piece back in place and went outside with the AIM-4170C, disconnected the 90 foot length of coax from the MFJ pass-thru and connected it directly to the analyzer. My readings were fairly consistent with what I got yesterday on the patio.

So, I'm pretty confident that this variance in SWR and impedance is due to it being connected to the MFJ pass-thru, but why? This thing is constructed such that all coax cables connected to it have their outer conductor in common - it is an aluminum plate sandwiched between a wood frame. This is the only thing I can think of, but then again, all my equipment is tied together with a ground cable, so what's going on here?

Buy a real antenna and put up a pole or a tower.

J Pole antenna's are used to teach theory.
If you have the only repeaters you wish to talk on in your neighborhood in your back yard, the J Pole antenna will work just fine - regardless.

But if you are a real ham - you will want to talk on as many repeaters as you possibly can, which means talking at distance, which means putting up a real antenna with some kind of gain and having it higher then everything else in the neighborhood.

Kenwood 7950 - geesh that thing is an antique..

A piece of rigid styrofoam and a coupler.

Try a sign shop or a place that makes walk in coolers / refridgerators.

Why not just drill a hole in the wall / or take out the coupler and put in your own coupler.

The pass thru panel allows you to run cables through the windows - but how do you keep the air from escaping through the gap at the top of the window?

The window is still open at the top, even when you have the hole plugged at the bottom.

I had a one of those antennae you are talking about, when I was younger and lived in New Jersey, a long time ago. It was a Cushcraft A-147-22, two meter beam on top of my 70 foot tower. But that was when I was young when I could climb a tower and lived in a community that allowed towers and antennae. I still have the Cushcraft, A147-22 stored in my attic along with a Mosley CL33.

Now that I am 80 years old, and live in a different kind of community in Florida, I feel fortunate to have ten acres of pine woods behind my house where I can hide a few antennae.

Do I yearn for the old days, when I had a tower that I could climb and real antennae. You bet. But, time moves on and dealing with that sometimes calls for compromise..

Yes, the Kenwood 7950 is old but it still works and puts out 45 watts. And, I was able to find an after market subtone board that will give me three subtones. How lucky can one old man get? I know, two meters has come a long way since my hay day, but at this point in my life, I would be satisfied to be able to contact my Ham friends on the East coast of Florida, 50 miles away when the sun is high in the ski.

I can always use HF when I want to talk DX.

I think I have found the culprit. But first, I want to extend my thanks to the many folks who have responded to my post - I really appreciate the input. And I came away from this with some great ideas!

This morning I had some time to do a bit of testing. I re-measured with the AIM 4170C connected to a six foot length of cable, the other end of which went to the MFJ pass thru. On the outside, the coax connected to the pass thru ran about 90 feet to the antenna. My readings were the same - impedance about 75 ohms, SWR pretty flat, but up around 1.6:1 across the whole 12 meter band. This is consistent with what I saw yesterday afternoon.

I unhooked the six foot coax, opened up the window, and pulled a foot or so of that 90 foot cable into the shack. Hooked it to the AIM and re-scanned. SWR still flat, but under 1.5:1, and the impedance runs around 38 ohms. At the suggestion of my buddy K6PJV, I unhooked the 90 foot cable and placed a 2 inch barrel connector between it and that six foot coax and connected it to the AIM. Readings went back to where they were when connected to the MFJ pass thru. I changed the six foot coax out for another piece, about 10 feet long. Same readings. I tried a longer (3.5") barrel connector - same readings. Well, whadda ya know!! The MFJ uses a 3.5" barrel connector to get the cable inside, too. And it is these darn double female barrel connectors that appear to be what is giving me these inconsistent readings. At this point I have to say it is more than a guess - it is pretty much proven by the testing I just did.

OK, let me be clear about one thing: no, I am NOT worried about having an SWR that is 1.6:1 instead of 1.4:1. :-) That falls into the realm of "BFD". And yes, my Elecraft KAT500 auto tuner has absolutely no problem matching things and presenting the KPA500 with a 1:1 SWR. My intentions for the original post were to see if anyone had an idea why things were different between "direct connect" and MFJ pass thru connect. It appears the the barrel connector(s) cause it.

I can probably get the original 1.4:1 SWR at the back of the KAT500 by eliminating the MFJ pass thru with it's barrel connectors. But is it really worth it? I have six coax cables, a ground cable, and the 14VDC power cable from my solar panel to deal with if I replace the MFJ pass thru. Building my own pass-thru out of Lexan or fiberglass is certainly an option. And, since I've maxed out the coax "ports" on this MFJ thing, I might just do that, but not by using barrel connectors!!! And yes, the window "was" open at the top when first installed, but I placed a fitted piece of foam insulation at the top and resolved that problem. The horizontally sliding window locks also fit into one of their grooves with the MFJ in place, so it isn't as if the window could easily be opened up. Other than the barrel connector issue, I have no major gripes about that MFJ unit.

On the antenna height - yes, going higher would make it perform slightly better, but in my situation, it isn't gonna happen. We have CC&R / HOA regulations and as it is I'm pushing the envelope with six (yes, SIX) outside antennas: an 88' long doublet at 45', an 80 meter Inverted L, a 160 meter Inverted L, a ground mounted Hustler 5BTV, a 5/4 wave 144 MHz vertical, and now this Moxon beam for 12 meters. However, the EZnec statistics for this antenna, at 24.900 MHz show that there is only a difference of 1.3dB forward gain and 1.7dB

F/B when dropping from 1 wavelength elevation (39.5 feet) to 1/2 wavelength elevation (19.75 feet). I'm just about 1/2 wavelength as it site now. I might be able to push it up another two feet, but..... would it really matter...?

So, for now, I think that's the end of it for me. Now, if only the 12 meter bad would open up. Arrghhhhhhhh!!!

73, and again, thanks folks.

Yes, the 7950 is old but a goody. I used one mobile and fixed in the early
80's. Actually had 5 units, pulled them out of box to use mobile to
hamfests and then sold them on my table.Along with my Skylane Quads.
No 2 meter activity here except for the wife and I car to house.
I use HF to talk with old friends and many new ones. From here every
contact is DX.

The pass thru panel allows you to run cables through the windows - but how do you keep the air from escaping through the gap at the top of the window?

The window is still open at the top, even when you have the hole plugged at the bottom.

You use the same thing that you used for the pass thru, remember I said to get a sheet of polycarbonate (Lexan) from the hardware store, home depot, lowes,. Cut a 1 wide strip of poly and seal that top gap. Also for you info the stores carry a removable , clear caulk for temporary installations. You can install it and a year later peel off the sealer and change things.

Next question??

Rich,

I sealed the wind/cold/heat out with a strip of insulating form that I jammed in at the top of the window works pretty well. But, if I re-build my pass-thru it won't be with barrel connectors for the coax! A sheet of Lexan or fiberglass, holes drilled through for the coax, and then slit down the center will work. But I'll probably keep it as I have it now, unless I somehow come up with a seventh antenna!!! :-)

You are getting it Jim, I used the foam at the lower open joint where it is window to frame and the polycarbonate strip with removable caulk at the top where the window latch is. Next trick if you just RTV your coax thru the pass thru you might need to stabilize the coax. Again I used a small strip of poly and attached the coax cables with some adell clamps. Then the strip is supported with 1/16 steel cables up to the roof overhang. Show and tell picture follows. The small white wire in picture is for something else.

The inconsistence readings is cause you do not have 50 ohms at the antenna end ... and then along the coax there are points interchanging every quarterwave length of the line with impedance around 80 ohms and 35 ohm (or in that range) ... and the changing is not caused by the barrel connector but with the changed length of the line and the not 50 ohms input!!!

A real test would be you have on length of cable with barrel connector (as you have now with the pass thru) ...

And the same length without a barrel connector inside (same length as the LONGER cable in previous test!)

If you would slightly change the antenna (to get closer to 50 ohms on the antenna end of the cable) ... then you would not notice changing the length, adding 1 or 2 barrel connectors, etc. ...

... now a complete different question ...

Why you did erect that 12m moxox?? On nearly the same space you could build a spider beam or hexbeam for 3 or 5 bands ...

And if you put that on a metal pole ... and all elements are connected to boom .... then this antenna makes a nice topload to feed the pole as a vertical :-)

I have tested this with several lengths of coax on the radio side of the barrel connectors. Some six feet long, some 15 feet, and another one close to 25 feet long. In EVERY instance, the SWR is in the 1.6:1 range and the impedance is around 75 or so ohms. With no barrel connector and several different lengths of coax directly between the AIM 4170 and the Moxon, the readings were consistently 1.3:1 and just under 50 ohms. But as I mentioned, these differences are not worth my worrying about. If I were running 100mw output, I'd be concerned about every 100th of a db, but I most often run 500 watts CW on 12 meters.

Why a 12 meter Moxon? Several reasons. First, it is the band I am most interested in completing my Worked All States on. ALready have WAS on 80, 40, 20, 15, and 10 meters. I am trying to complete it on 12 meters before the sunspot cycle (as crappy as this one is) leaves us. I'm 65 years old - who knows if I'll be around for the peak of the next one! :-)

Second reason - quite inexpensive. I built this one for less than $100USD.

Third - a single band Moxon for 12 meters is pretty inconspicuous. It isn't too large and I'm able to have it placed in a spot in the yard where it is hidden by several redwood trees. A hexbeam or spiderbeam would have a larger turning radius and would not fit in the allotted space. If the restrictions were not there, I'd have a nice tower and a multiband (30-17-12) yagi on top, but alas - that isn't possible. So, the Moxon was my antenna of choice. And it does work quite nicely. First QSO: 3D2RH, Fiji - on the first call in a moderate pileup.

uesed to be able to get a 2 or 3 " square gray foam strip at most any hardware or home improvement store that was used to seal the gap when you had a window A/C . they may still have them but be prepared to find it on your own . I needed a few about 5 years ago and the staff had never heard of them .

Sounds like nice stuff... I'll keep it in mind for other projects.

However, the intent of the metal plate is to create a common connection point for the shields of all the cables. A point which then can be run to your lightning protection grounding point.

If you used just the fiberglass sheet you'd then have to separately tie all the shields together to be run to your lightning ground. Something you definitely do NOT want to do through the connections inside the shack. We never, never invite lightning in for lunch... it's really a lousy guest!

Stan

Another quick idea to replace your metal plate... McMaster-Carr (and others) sell fiberglass sheet material. If you bought a 2'x3' sheet of 3/16" thick G10 you could cut it to size and install all the jacks you need. This stuff is very strong, stiff, resists water uptake, is flame retardant and is UV resistant. It takes paint well if you tough up the surface. We in the boomerang building community love this stuff.

No offense intended but there are many facets to Ham Radio.
My most used antenna is a J-Pole stuck into a short piece of masting, about 6 feet. It reaches the local repeaters fine using about 10 watts. I can talk to my local friends very well and I have managed to stay out of trouble with lightning.

If I change over to an 11 element yagi at 60 feet I can be a nuisance across several states.
Most of those operating older equipment do so with great pride. My ICOM 32-AT HT Out performs Every modern HT I have seen. It also runs from a number of power sources including Alkalines from Dollar General.

I do appreciate your enthusiasm though!

Got to agree with you. Then again I have been "hamming" for 37+ years now.
Seems the "new" guys are taught to try and communicate HF distances on
VHF/UHF frequencies. But even those ways of communicating are changing too.
Look at the WAN repeater systems popping up. And all the digital modes of
communicating with 5 watts-around the world!
At my new QTH, I am high up and run my 5 watt IC-O2AT into a J-Pole at 12
foot. I can WORK repeaters in 4 states! (PA, OH, NY & WVA.) At my old
QTH...stacked 11 elm 2 Meter beams at 55 foot, on a tower, fed with 1/2 Helix
and a 300 watt amplifier...had "trouble" hitting repeaters in Pittsburgh,
which was 35 air miles away. (Cabot was down in a "bowl.") VHF/UHF is all
location, Location, LOCATION! The higher, the better. (The VHF array is stored
away.) I could just imagine what problems (for me,) operating the beams AND
power would cause me "up here."
I have "upgraded" my ham knowledge over the years, but don't pretend to
know the ham radio the young guys are more comfortable with.
I miss the old nights of the glow of the tubes in my "separate"
transmitter AND receiver. And the old teletype banging away beside them. I suspect 35
years from now THESE ham's will be saying the same things I do now.
Enjoy the hobby!
73,
Dave-KJ4PF

jferrell13@... writes:

No offense intended but there are many facets to Ham Radio.

My most used antenna is a J-Pole stuck into a short piece of masting, about
6 feet. It reaches the local repeaters fine using about 10 watts. I can
talk to my local friends very well and I have managed to stay out of trouble
with lightning.
If I change over to an 11 element yagi at 60 feet I can be a nuisance
across several states.
Most of those operating older equipment do so with great pride. My ICOM
32-AT HT Out performs Every modern HT I have seen. It also runs from a number
of power sources including Alkalines from Dollar General.
I do appreciate your enthusiasm though!

I agree.

One of the reasons I did not use the 2 meter beam very much when I lived in NJ was that I would bring up more then one repeater at the same time. NOT GOOD. Of course, many years ago before most repeaters used a sub tone frequency.

As far as the Slim Jim JPole that I intend to use here in Florida. My situation is entirely different. I live in a restricted community that fronds on outside antennae. Of course, they don't want to talk about TV satellite dishes. I am lucky to have 10 acres of pine woods behind my property where I have 2 dipoles and a 5 band vertical. Hanging the Jpole antenna is a convenient way to get the Jpole up high and at the same time remain inconspicuous.

I'll see what happens with the Jpole hanging from a tree limb. If I get reports of flutter or fading, It should be an easy matter to stabilized the Jpole with 3 or 4 small diameter cords to a few surrounding tree trunks.

God, I love this hobby.

Good morning all,
Just a quick question for the group...In the last week or so I was forced to move my station from one room to another room which is closer to the antenna system. I have the Yaesu 897D...with a G5RV,jr and the MFJ-1622 vertical. I was running approximately 100' of coax from each antenna to the station. Now that it is closer I find I do not need this much cable. Right now I have the excess coiled up under the desk, however, when I turn on the radio and tune through the bands I am not receiving anything. I suspect it is the coiled cable that is not allowing me to receive. My question: Should I buy some smaller length of coax (funds are an issue as well) or just coil the excess outside at the fed point?
Suggestions...thoughts....funny remarks....snide comments....I will read all but may not respond to all.
Thanks for all you guys do.

Coiling the excess cable should not prevent you from hearing anything.
You need to check the connections, connectors, etc and make sure everything is still correct.
Moving coax can sometimes cause a kink and thus a short internal particularly with foam coax.
Also connector center pin solder joints sometimes are not good and come apart when moved.
Quick test is to connect just the outside shield to the center pin of the receiver connector. You should hear signals. Then do same for center wire of the coax only. If you hear signals both ways you maybe Ok, if not check out why not.

I disagree. All the coil of cable should do is act like an RF choke to any RF on the OUTSIDE of the cable. I.e., common-mode RF. It should not effect any signal from the antenna to your receiver.

One way to check for a bad connection is to check what your SWR is on those bands you operate. If it is unusually high or very different from what it was before you coiled the cable, then I would suspect either a bad connection, or, perhaps, if your coils are very small, and the bends are too short, perhaps a center-conductor has "migrated" to the point that it shorted out against the shield.

> My question: Should I buy some smaller length of coax
> (funds are an issue as well) or just coil the excess outside at the fed point?

Why can you not whack it off at the necessary length and install the necessary fittings? You could then install fittings on the shorter pieces and eventually use them for jumpers or etc.

I am 100% certain that the problem is NOT the coils in the coax, but some other problem, perhaps related.

Make that 110% certain. Only the shielding braid of the coax *might* act as an RF choke, depending on how small the coil was and how many turns. All the so-called "ugly baluns" in the world prove the signal on the center conductor is in no way affected by the coiling (except for some very-slight loss--undetectable by ear--owing to additional length.

I agree with Ken that you should check all your connections. You can also test the coax itself in various ways. The simplest is to use a clip lead to jumper between the center conductor and the cable-connector collar on one end and to read the DC resistance on the opposite end. For 100 feet, it should be right around 1 ohm (20AWG solid copper =~ 0.01 ohms/foot), though it could read a bit more depending on how solid you make your test connections. If you read much more than 1 ohm (say, 10 ohms), then something is screwy. If your meter reads open (infinite ohms), then the center conductor is broken somewhere along it length, or there's no or a poor connection at the plug on either (or even both!) end.

There are some sophisticated instruments that can pin-point a break along its length (Google: TDR), but if renewing the connections on the plugs (by replacing) doesn't fix the open reading, then you probably need to buy new cable. Keep the old, though, since there could be usable lengths you could use later (mobile installation, shack jumpers, etc.).

The best thing would be to shorten them. If you can't do that squeeze the coil together like a bow tie and tie it that way and try it.

James: Sorry, I got in late on your post's, think I might have missed one.
1. How old is the coax? 2. Brand & model number of the coax? 3. How "tight" did you make the loops?
IF older (or cheaper) coax, and/or IF it was in a warm environment (hot shack, "smoker" shack-nicotine DOES do a real number on coax over time.) When you coiled it...it's possible the center conductor "migrated" thru the insulation to the shield. Easiest (and cheapest solution,) bring the coax in from the outside, measure what you need, and cut from the ANTENNA side of the coax. Put on NEW high quality PL 259's (white Teflon center insulator-NOT Radio Shack JUNK. Good connectors are about $5 each in my part of the US.) And your done! With no signal at the receiver, it sounds like the center conductor & the shield have "mated" somewhere in the cable. Try this: with receiver tuned to a some strong signal, (WWV 5.0 Mhz at night, 10 or 15 mhz in daytime.) Unscrew the coax from the back of your receiver. Now, just stick the center conductor in about 1/8 of an inch. Make sure nothing else touches! You should hear "something" unless the short is very close to the rig. The stronger the signal-the further away from the receiver towards the antenna your short is. This happens because you are making the coax become the antenna. (Much like the headphone cord becomes the antenna for the walkman's of a few years ago.) Now everybody wi-fi's the music to their cell, tablet, laptop, etc. Pulling a signal "out of the air" is a dying thing!
Just a few things for you to consider.
Do the receiver test FIRST. It's a bitch to solder new connector's onto BAD coax, THEN have to remove them and do it again.
Keep us posted here on what YOU find, and what YOU did. (And I still would like to know WHOSE coax & model number it is...could answer a LOT of question's.
Good Luck!

James: Sorry, I got in late on your post's, think I might have missed one. No problem. I don't think you missed too much. 1. How old is the coax? One length (goes to G5RV,jr is almost 2 years old. second length (going to vertical) is less than 6 months.

2. Brand & model number of the coax? Both lengths are RG8X . Neither have brand names on them. The oldest is a grey color with the following printed on it : 95-74400 RG8X 95% OEM/USA The second one (newest one) is black and has the following printed on it: CCI991020E118963-HRG8XMINI COAX17AWGTYPE CM(UL)AWM1854LL53149 CSA CMH FT1--686987 Both lengths are from Cable Experts company.

3. How "tight" did you make the loops? Coils are just standard 6-8 inch coils not real tight.

IF older (or cheaper) coax, and/or IF it was in a warm environment (hot shack, "smoker" shack-nicotine DOES do a real number on coax over time.) No no smoking in shack...standard Southern California weather with A/C on when needed (my shack is also my bedroom in a two bedroom apartment I share with one other person).

When you coiled it...it's possible the center conductor "migrated" thru the insulation to the shield. Easiest (and cheapest solution,) bring the coax in from the outside, measure what you need, and cut from the ANTENNA side of the coax. Put on NEW high quality PL 259's (white Teflon center insulator-NOT Radio Shack JUNK. Good connectors are about $5 each in my part of the US.) And your done! Yea...I pretty much figured out I was gonna have to do this...thanks :-)

With no signal at the receiver, it sounds like the center conductor & the shield have "mated" somewhere in the cable. Try this: with receiver tuned to a some strong signal, (WWV 5.0 Mhz at night, 10 or 15 mhz in daytime.) Unscrew the coax from the back of your receiver. Now, just stick the center conductor in about 1/8 of an inch. Make sure nothing else touches! You should hear "something" unless the short is very close to the rig. The stronger the signal-the further away from the receiver towards the antenna your short is. This happens because you are making the coax become the antenna. This is a test I never heard of and anxious to give it a try...sounds like an interesting way to test shorts when you don't have a lot of test equipment.

(Much like the headphone cord becomes the antenna for the walkman's of a few years ago.) I remember these...in fact my "smartphone " has an FM raido app that refuses to activate unless I plug in a headphone.

 Now everybody wi-fi's the music to their cell, tablet, laptop, etc. Pulling a signal "out of the air" is a dying thing! Yea...this is why I am anxious to figure this out so I can begin to "pull signals out of the air".
Just a few things for you to consider.
Do the receiver test FIRST. It's a bitch to solder new connector's onto BAD coax, THEN have to remove them and do it again.

Hi James,
I would like to suggest you look elsewhere for your loss of signals. I seriously doubt it has anything to do with your coax. If nothing else has changed other than you now have some coiled up that used to run straight, it wouldn't affect things so drastically.
My thought is that in making this move, you did something to your rig that is the fault. Some control or function has been reset. It will probably something really simple/dumb:)

Kathy probably has the answer, but try this; go to Radio Shack, Lowes, Home Depot, Ace, or another hardware and get a *Multitester *(analog, preferably) and turn it to the resistance scale (Ohms or Ω) check for a short circuit by touching one probe to the center conductor and the other to the shield/ground. The needle should not move. If it does, and goes across the scale, you have a short, and need to get to work on your coax.

For my 2 cents:
1. When you changed rooms, you probably unplugged the radio, and perhaps lost all your settings.
2. When I made my last move, (from Indiana to Michigan), the radio got bumped somehow--causing my RF gain control to close.
Just some thoughts from on old geezer, should not be taken seriously, by any sain person.

Kathy probably has the answer, but try this; go to Radio Shack, Lowes, Home Depot, Ace, or another hardware and get a Multitester (analog, preferably) and turn it to the resistance scale (Ohms or Ω) check for a short circuit by touching one probe to the center conductor and the other to the shield/ground. The needle should not move. If it does, and goes across the scale, you have a short, and need to get to work on your coax.

What I do is use a similar block on the window but run the coax straight thru with a sliding block with cut outs for the coax.

Thanks for all the advice and replies to my question, I will be setting up a single loop , fed with open wire feeder, to a tuner and 4:1balun, ffor broad band use.

Happily I have 3 extension pipe masts and a boat mast for the 4th cnr, which should give me an antenna height of about 7meters.

The antenna will be made from 1.5mm sq insulated multi strand wire , which is used in 15amp 240 extension leads over here , I have found that this wire while not the lightest, lasts for years , and with stands the elements quiet well.

The total length should be in the region of 45 to 5ometers 140 t o 155 ft at about 23ft above the ground.

Be another week until I can get to getting it orginized due to renovations in the house.

Cheers & thanks

After many years of professional lab grade testing of cables, connectors, etc., with quality test equipment, I conclude:

Don't get to bothered about impedance "bumps" at HF frequencies. For most connectors/cables of reasonable quality, it is minimal and can be ignored. Even at VHF frequencies, it's not normally enough of a problem to worry about.

32347. Connectors - N VS 259

Yahoo group: ham-antennas (2014)
Date: 2014-05-05 12:38:46 UTC
From: Scott Myers
Topic: 32287 Message: 32347

Starting new thread.

Agreed! The impedance bump is so small that you'll not see it in the grand scope of all the feed line.

I've swapped out to mostly N-connectors where I can (especially outside) not because I am worried about impedance bumps. Rather, I care more about keeping moisture out of the connection and a good electrical contact that I am 100% positive is good over time. There is never any question that an N-Connectors is making solid contact once you feel the silicone seal touch and compress. On 259's, I don't know how many times I've had bad barrel thread engagement and had to rely on channel locks to make sure the ground side was tight. And the slip fit and potential for a solder bump on the center pin of a 259 is also other areas of potential problem for a bad connection.

I still weather seal even an N-connector with silicone tape even though it is much more weather tight than 259/239 interfaces.

But, the N-connectors are quite a bit more pricey and have a lot more parts to deal with. 259's and 239's still work, they are just more prone to a weak connection. I still have a lot of 259's hanging around in the shack because all of the equipment still uses it.

But I have settled on all Amphenol 259's and Teflon insulation. I've had trouble with fit and threads on the no-name brands.

Well I know this is very old now but I just found it in my inbox again.
(Ask the WWW I have no idea why)
Back in the *ancient *days of Amateur radio *(1964)* when I had my novice
call KN7SVA
the rule book stated *200' maximum height above terrain!*
Since I got back into it in 2009 I have not paid attention to
antenna height regulations
as I do not have the money to go more than 50' push up if that much.

I was just surprised by it and could find no information on when it had
been changed.

Adrian - it would be interesting to know. Yes there was another rule we had to learn too - that
you couldn't erect any antenna over a certain height if you were within X00 yards of an airport, if I remember correctly.

Does anyone know what the correct FCC rules are nowadays?

Nothing has changed except for the arrangements of the rules,
referring you elsewhere.

If you wish to install an antenna support that tops out at 200 feet
AGL or more you must get FAA clearance, seldom given to HAMs alone, you
can mount your antenna on any existing support structure of any height
that already has FAA clearance.
If you get permission to install a 400 foot tall tower for your
commercial FM radio station, you can put any HAM antenna on it
(anywhere) as long as it doesn't increase the structure's height.

I have been in touch with the chap I got it from and he said he did have 2 fascia and there was nothing on the other side when he took it apart and changed it for the South fascia.

That's interesting, so still looking for a copy!

Last Saturday I put up an 80 meter loop nominally 20 feet above ground. It tuned all the usual suspects (all except 30 and 60 meters) with the built in tuner on a Kenwood TS 480 or an LDG Z100 autotuner. My first contact was
Somalia and Monday morning I had a strong contact with Finland.. Both contacts were on 17 meters. On Tuesday I could not get the antenna to tune on the bands below 15 meters and my MFJ 259 showed SWR to be 2.5:1 to just less than 3:1. The antenna consists of 300'+ of insulated 14 ga insulated copper wire attached to a 1.5:1 balun fed with 20' +/- of coax. All connections are tight. Any ideas as to what made the antenna go from hot to not?

I would suspect if it rained you have water in your coax.. Had it happen recently so thought I would throw that in.

Good point about the balun and condensation . The first ones I made were PVC pipe caps and sealed all around, 2 years later they drew moisture. Now I used a PVC box w/gasket and leave one screw hole in the bottom SO-239 open.

Hi guys , need some ideas and advice, want to work a QRP contest with 4SQRP tonight , supposed to be TSTORMs , have Metal roof, would an Antenna put up in the attic work ? Have anyone heard about this challenge ? Would or could it radiate better out of the sides with no metal ,(just metal Vent at both ends), ? Am i better off using a loop inside ? 40 meters-10 , have a portable dipole i put together and it tunes up well , have not used it in a QSO yet. Appreciate your help, AJ - oh yeah my call has Changed to W5HEH-
was my Uncle's call sign, He was in Radio in the Navy, and became an Electronic Engineer , he mentored me and had Big Boat Anchors that lit up well . Man were they Heavy ! hihi.wish i still had them .

I think that any attic antenna with your metal roof will do very poorly
because of the coupling/detuning that will happen.

I agree with Geoff and an antenna in the attic under the metal roof is
unlikely to work very wel, OR

At QRP power levels I would be tempted to try actually loading the metal
roof itself :-)

Or use it as a "top hat" for a vertical radiator

32369. Aluminum Tubing Coating

Yahoo group: ham-antennas (2014)
Date: 2014-05-11 21:29:56 UTC
From: w6jhb@...
Topic: 32369 Message: 32369

In my previous (working) life we had a Moseley Pro96 monster antenna on a tower on top of an 11 story building in downtown Oakland, CA. It was part of our ham club's antenna system. We were located only a few blocks away from SF Bay and the salt air tended to corrode outside metal fairly fast. So, when we mounted the Pro96, we used Penetrox A on the slip joints and to protect the exposed aluminum element parts, we coated everything with Flood's Penetrol. I also used it on a Hustler 5BTV I had roof mounted at my home in Martinez.

I moved to Folsom four years ago and am now preparing to build and install a quarter wave vertical for 30 meters. I can get the Penetrox A locally, but it appears the the air quality Gestapo out west has outlawed Penetrol. If you look at it on Amazon.com you'll see that it can be purchased there, but not shipped to AK, CA, or HI. That's just wonderful.

Does anyone on this reflector have any ideas what a good replacement for Penetrol might be that I can use to coat my exposed aluminum tubing. Although we don't have the salt air to deal with here in Folsom, I think it's still a good idea to give that aluminum a coat of some sort…..

After adjusting, tuning, pruning, and no-ox'ing slip-joints on my antennas, I paint them with black Rustoleum. I prefer them black anyway, and Rustoleum was made to protect metal. I might add that air quality is more important than preventing corrosion on hobby antennas, especially when there's lots of alternatives.

Todd,

Thanks for the tip on using Rustoleum on the bare metal. Our local Ace Hardware has some spray paint in green, black, and brown tones sold as "camouflage paint" - I've used it on some PVC antenna projects in the past. With any luck it'll be a Rustoleum product and I can use the same stuff. I "hid" a 144MHz 5/4 wave PVC vertical and some spreaders for an 80 meter Inverted L folded counterpoise using it and the results were very impressive.

And I agree that air quality is important. However, the amount of pollution given off be a few hobbyists protecting some aluminum is so very, very minute compared to the amount of crap put in the air by cars, buses, and trucks. If the Air Quality people really wanted to clean up the air, they are aiming at the wrong target. Ever follow some disgusting fume-belching semi through town? THAT is the stuff that needs to be addressed, not a few folks trying to thin out paint or coat aluminum. If it were only allowed to be sold in pint containers that would have helped, but instead the entire population has had it taken away.

Yeah. The shipping to AK and HI is verboten because of air shipment.
To CA, it's because of religious rules.

> Does anyone on this reflector have any ideas what a good replacement for Penetrol might be that I can use to coat my exposed aluminum tubing. Although we don't have the salt air to deal with here in Folsom, I think it's still a good idea to give that aluminum a coat of some sort…..

Well, the MSDS for Flood's suggests that it is polymerized linseed
oil diluted with Stoddard solvent and naphtha (both essentially paint
thinner), so you could make a reasonable approximation by getting some
Birchwood-Casey TruOil from a gun store (there still are a few in CA)
and diluting it with paint thinner, until it reminds you of Flood's,
if Nanny'll let you have some paint thinner. Basically, Flood's sounds
like varnish (say, McCloskey's Man-o-War spar varnish) cut with Coleman
stove fuel (which is more hazardous than paint thinner, watch the open
flames -- see what happens when safe substances are made illegal, but
dangerous "folk" substitutes are not?) Gee, small quantities could be
cut with cigarette (GASP!) lighter fluid. Then you wouldn't have an
unused 7/8 of a gallon of thinner or stove fuel in your garage. :-)

Or do what everyone else does, and smuggle it in from the free world.
Sometimes people from CA visit Nevada, I seen to recall, visiting the
multiply attractive aquatic resorts, relaxational facilities, hardware
stores and other attractions.

73 and sympathy, (ex-CA) Dave AB3NR

Thanks for all the ideas for an Antenna that would protected from lightening strikes, maybe i did not make myself clear, hihi, loading the Roof is interesting, we have an uncoated, (except for the rust , hihi) tin roof on one of our out buildings , yah we live in a rural area with a small farmstead, we moved from a large metro area 11yrs ago , i was born in Oakland CA went to HSchool in Sacto and spent way too many years in So,Cal, what i really want to build is a Delta /Skyloop, and just disconnect when T Storms come by , will start it next year . Yes i will try a Vertical for the fun of it and use it for portable and i have plans for a Loop, got some old Variable CAps recently so i am getting it all ready for winter projects . Appreciate the tips and advice i learned some from it , which makes it interesting to use in this fun hobby, 73s AJ W5HEH, yah new call sign.

If I remember correctly, WD-1 “commo wire” has a mixture of copper and steel strands to give it strength.

Sigi,

I got a loan of one of the triple mag mounts but I'm not getting a good earth. Before if I use the mfj1979 I could adjust it for any of the bands and get an swr of around 1.6 or less. Now I've changed my car I'm getting no where need this so looks as if ill need to make a shunt coil up to increase impedance when I get the length of the antenna so that X = 0 or close as.

32388. Signal Corps rhombic book

Yahoo group: ham-antennas (2014)
Date: 2014-05-13 11:29:39 UTC
From: Mike Markowski
Topic: 32388 Message: 32388

Hi all,

Are any interested in a pdf of

"Construction of a Rhombic Receiving Antenna," US Army Signal Corps, March 20, 1943

It's 37 pages long, 15 pages of which are text and the rest tables & drawings, and is7.3 MBytes. It lays out the heavy duty design of rhombics as built by the then-US War Dept, not a backyard ham antenna project! But a ham or club lucky enough to have enough land and spare change might make use of it. Also, it contains no theory whatsoever. "Rhombic Antenna Design," by AE Harper, Bell Telephone Laboratories, 1941 is a good and similar vintage companion in that regard. Harper's report also contains construction details.

Before US Army Ft. Monmouth, NJ closed a few years ago I enjoyed using their one surviving rhombic of the 2 originals. Thinking of how much fun that was got me reading up on rhombics recently. Some photos of that shack just prior to shut down:

It would be helpful to know:
Resistance per M or ft
diameter of wire
tensile strength

At less than half a cent per foot it does have an attractive price.
1640 feet of that is about the same price as 500 feet of #14 insulated copper wire locally.

Do any of the folks on this group know one or more reputable suppliers of aluminum tubing that sells online or locally to the Sacramento area? I recently decided to build a 30 meter 1/4 wave vertical using aluminum, not wire. A place in Sacramento (Blue Collar Supply Inc.) has a web presence and shows lots of the stuff on their web page. Yesterday I drove over there only to find that (1) the largest OD tubing they have is 1-1/4", and (2) most of the shelves with various sizes smaller than that were empty - a very frustrating trip, indeed.

I also checked at OnlineMetals.com and they didn't have a great variety, either. So, I wound up going to DX Engineering and ordering my tubing from them. Granted, they have a LOT of different diameters and the prices "seem" to be in line, but it would be nice to see if there is any competition out there and what prices other places are charging. Ideally, a company somewhere in the Sacramento, CA area would be great - the shipping fees for long tubes is out of sight.

Any info would be appreciated.

Thanks, Jim / W6JHB

There's a MIL-SPEC or something similar for this wire out on the wild internet somewhere. Sorry, lost the URL, but it came up pretty easily with the google. I seem to recall a figure of 48 ohms DC resistance for "1000 loop-feet" of wire, which I take to mean a loop of 1000 feet length. Whether this includes both conductors in parallel or what, I don't know.

Structurally, it is a twisted pair. A given wire has seven strands, three (I think) galvanized steel, four tinned soft annealed copper. The specification gives their diameters, depth of coating, dielectric strength of insulation, resistance to moisture, and so on. The insulation is nylon, I think.

When new, this was pretty fancy wire. It was intended to work, even after being laid down in the fetid jungles of SE Asia, without kinking, shorts, opens or breakage. You don't send your comms man out to be shot at to lay crummy wire. Not cost-effective, also bad for morale, and loses battles.

> At less than half a cent per foot it does have an attractive price.

It does. But this stuff is used. But we know how to test it.

> 1640 feet of that is about the same price as 500 feet of #14 insulated copper wire locally.

If you can't find the spec, get back to me, and I'll hunt around my browser history. Shucks, do it now, lazybones.

hmmm: Here's something: http://www.associated-ind.com/pdf/FIELD_WIRE.pdf
That's a modern catalogue entry.

Thanks, Dave. However, I just scanned through the entire document and have not yet found the definition of "loop-feet".

I have never heard the term before this.

Anyone?

32395. Portable vertical HF antennas for RV, 18 ft or higher

Yahoo group: ham-antennas (2014)
Date: 2014-05-13 20:33:59 UTC
From: wa1rkt@...
Topic: 32395 Message: 32395

Looking for a portable vertical HF antenna to mount on the back bumper of a 30-foot RV trailer for use from 3-30 MHz with an autotuner. Desired height is 18 feet or higher, obviously only for not-in-motion use. The antenna should be stiff enough to be self-supporting to its full height, yet flexible enough that it can be bent over the roof of the trailer and the top-end tied down for in-motion or NVIS use. Fiberglass construction is preferable over steel.

I tried a 108" stainless steel CB whip with some MFJ-1600T mast extenders but the MFJ mast extenders, even just one of them, are nowhere near strong enough to support a 108" whip and hold it vertical.

I looked at a couple of Shakespeare marine HF antennas but they don't look like they're able to be bent over and the tops secured, for in-motion or NVIS use.

Any ideas?

Rick WA1RKT

Hi Rick.

I mounted a Hustler 5-BTV (10,15,20,40,80 Mtrs) on the shaft of the motorized hitch lift on my 1987 Avion 30P RV. I attached the antenna mounting base plate to a 1/4" thick aluminum plate with two SS U bolts. When we were on the road I stored t he antenna in a 5" diameter VC tube that was bolted to the frame under trailer. I could have the antenna in the air within 10 minutes after setting the trailer up on the campsite.

It worked out well for me.

Photo attached.

Rick, I use an Eagle One antenna on my motor home. I don't transmit while driving either . The ant mounts on the ladder and extends to 32ft. All kinds of variations to add another 30ft for 75 meters. I use a4:1 UNUN that is homemade. Lots of manufacturers support & easy to deal with. Chuck Wq5B

Thanks, Bill. The problem is that this antenna will be used on a list of Civil Air Patrol and MARS frequencies, some of which are far outside of the amateur bands. Also we need to be able to bend it over and secure the top to something on the trailer, so that we can get at least some horizontal polarization for NVIS use... more often than not, we will be using it in the 4-5 MHz and 7.5-8 MHz ranges, for regional communications in a 30 to 150 mile radius.

I suppose a 30-foot aluminum mast on some kind of tilt-over base will work, if I can't find something suitable made from fiberglass.

Thanks, Chuck. The Eagle One does look like it should work. My question is this... is it flexible enough that it can be looped over and its top tied to somewhere near the front of the trailer? That way it could be used while in motion, and more importantly will provide some horizontal polarization for NVIS use on the lower frequencies.

Rick,

I added a photo of my travel trailer antenna mount. Very simple, two Glastic insulators and two muffler clamps with bolts welded on. My antenna for stationary use is a center loaded 33 foot telescoping aluminum vertical. It is loaded for 3.5 MHz with the center coil and coil shunted for 40 meters. I have tuned it out of band by using a series cap to above 4 MHz MARS frequencies and with a base coil to 60 meters. The antenna is in 6 to 8 foot sections with hose clamps. Just a thought.

No, it is not real flexible . No need as it travels fully collapsed
about 42 inches tall. Time to raise is just 3 or 4 minutes for this 70
year old . I use a IC 706 and a LDG auto tuner barefoot and talk world
wide . It tunes 75 but is weak , so I clip a 30 ft extesion to a washer
provided at the top and extend it toward the front of my 31ft motor home
. Then it tunes 75 with ease and is fairly strong. On 40 here at
home my signal with just the Eagle One is comparable to my full size
inverted vee hung with the apex at 70ft and sloping to about 40ft. I
would have never believed that if I had not done the test . Chuck
PS: what kind of travel trailer.....I spent 30 years
in the business Wq5B

Thanks, Chuck. That's kind of what I was afraid of. I sent the manufacturer an email asking about flexibility and he didn't answer, just said the antenna isn't meant for in-motion operation and that's all he said.

Most of what we do with that trailer is NVIS stuff, meaning horizontal polarization and relatively short range (but longer range than allowed by groundwave). It's relatively rare, although not unheard of, that we would orient the antenna straight vertical and use it for longer-distance comms. Thus we do need the capability to loop the antenna over the roof of the trailer to get at least some horizontal polarization.

As for the trailer, I'm not sure exactly what kind it is. It belongs to the New Hampshire Wing of the Civil Air Patrol, and they got it from FEMA... it was one of the trailers that FEMA used to provide people with temporary housing after Hurricane Katrina.

Why not try the 100w end fed 6-40 30' wire from EARC the emergency amateur radio club of Hawaii. About $50 delivered. A tuner required. All frequencys should be below 3:1

Use a Shakespeare 20' fishing rod and totally vertical or inverted L.

You might want one of these in your go box anyway.

They use coax shield as counterpoise so you need about 15' of coax.

I tried one out at home and was impressed for something you can erect in a few minutes.

I am very familiar with the FEMA trailers of that era . I built two RV parks there for Gov't Grain inspectors so they could return to work very soon . I was retired but contracting . I then oversaw the delivery of many trailers to both New Orleans and to Jasper ,Tx for staging . There were many trailers in Texas as we had our own hurricane just after Katrina . Texan's were thankful for what help they received and rebuilt their places quietly rather sit around waiting for more Obama bucks to be delivered . You must be using this trailer for a mobile EOC . My 75 meter mod is a cloud burner by design . I have another mod to allow ten (11)meter operations when in motion. I would think that 75 & 40 comprise 90% of your work and a little on 20 meters. Play with a loop some Good Luck Chuck Wq5B

32409. Will a loop give me a good signal?

Yahoo group: ham-antennas (2014)
Date: 2014-05-14 01:06:37 UTC
From: Alex Netherton
Topic: 32409 Message: 32409

Hi folks;
I am looking to get up an antenna for 160 meters, since my rig has this band - I never bothered with it because my former rigs didn't have it, and you con't miss what you don't have. I have tried a 1/4 wave wire, and got dismal reports.

I am interested in doing a loop (560 feet!), which I think I can do if I encircle the yard. I will feed it with a balanced lader wire and a tuner.

The question is, will it give me a decent take off angle, or will it be a "cloud burner". I will only be able to get it to about 40 or so feet in the trees here.

I know many crave an NVIS antenna, but I do not. I do not work MARS, and ARES is only part of my Amateur pursuits; I can get an NVIS up in a few minutes anyway if I need one.

So, for a 160 loop at around 30 feet, what will be my takeoff angle? Will I be stuck working 100 miles or less from my QTH, or will I be able to go further? Plus, what will it be on the other bands?

Thanks and 73

Because the loop is basically a horizontally polarized antenna at 40' it will be cloud burner. A better choice for working WAS and some DX from 4 land would be an inverted L. Sounds like you have a decent sized yard so maybe even two inverted L's fed in phase switchable broadside and end-fire. With a 45' high inverted L, I owrked 68 countries on 160M the first winter I put it up and that from what is known as the "black hole" (upper midwest) for 160 M. The other part of making the L work is ground radials at least 16 ..more than 50 is not worth the effort. An amp for 160 is also advantages more so than any other band...

Good luck and welcome to top band

Would I use the inverted L as a vertical with the feed point at ground level? Radials might be a problem, as the XYL might not like them strung out over the lawn. I do not think I can get the feedpoint above ground level. Would 2 groundplanes work? Maybe 4?

Would love to use my amp, but it (SB-200) only goes to 80 (slight frown...).

> lawn.

You don't string them "over" the lawn: you lay them ON the lawn. Within one year you will never see them again, except at the ends you connect to the feedline. My radials are now down at least 2" below ground level, and I never dug them in. I never had any trouble mowing over them either, even when I could still see them.

> I do not think I can get the feedpoint above ground level.

That's where it goes: ground-level.

> Would 2
> groundplanes work? Maybe 4?

Huh?

> Would love to use my amp, but it (SB-200) only goes to 80 (slight frown...).

Adding 160 to an SB-200 isn't all that difficult, but it IS time-consuming...there is plenty of room in the final compartment for a longer plate coil.

With my base-loaded 55' tall vertical, I've worked Europe on 160 with 100 watts.

1st think of the inverted L as basically a top loaded vertical with the feed point traditionally at ground level. If you really mean will two ground RADIALS work (a GROUND PLANE is is typically thought of as 4 or more ground radials) The answer is yes two radials will work but a high percentage (probably 50% or more) of your power will be lost in ground losses.

There are many ways to deal with the wires in the grass problem. I have used a old edger to cut slots which grow over in weeks. But the easiest solution I have found so far is 10' gutter nails to stake the wire flush with the ground every 3' or so.. Lots of work has been done but a lot of empirical evidence indicates the that around .2 wavelength is adequate for ground mounted radial lengths . Staked to ground the wires become nearly invisible after a couple of months and I have no problem mowing over them.

Rich, funny thing i just bought one of those Boxes at Lowes, i was thinking of a junction coax and grounding use mounted near Grounding rod and entrance into shack area. For Baluns, or UN-uns is a good idea . Last portable antenna i made recently is with all Twin lead w/feed line as well . i might try putting this one in the attic to see if i can out over the metal roof, or i might try an indoor loop first . 73s , AJ W5HEH

"Thanks, Dave. However, I just scanned through the entire document and have not yet found the definition of "loop-feet"."

I believe it means you connect the far end wires together and measure between the wires on the near end. They complete a loop, out and then back. 1000 loop-feet is 1000 feet out plus 1000 feet back.

Andy

Another antenna to consider is the loop with the feedline dropping vertical; then on top-band, tie the feedline wires together and feed them against ground. It is essentially a top-loaded vertical, which makes it like the inverted L but with a lot more wire (capacity hat) on the top part.

It has the advantage that you can feed it normally (differentially) if you want to.

NVIS isn't only out to 100 miles. You should get 400 miles or so with very good performance, and a lot more than that with somewhat more "ordinary" signal strengths (i.e., comparable to anyone else with a horizontal dipole).

At higher frequency bands, the loop's takeoff angle drops, turning into a decent DX antenna.

Unlike dipoles, loops tend to load up well on both odd AND even harmonics.

Andy

A trap inverted L would work very well, even with a fairly low vertical section.
My radials are buried under the lawn.
Basically just cut a W3DZZ in half and use those dimensions. If you want 160 then make a simple L/C trap with another 20 or so foot on the end.
Not forgetting at the higher bands you could get upto about 8db of gain.
I only run 25 watts but, yesterday for example I was getting -01 and -02s on 15 JT65.
My vertical is 32 foot high and the rest horizontal but I aim to increase the vertical section to about 40 to 50 foot, neighbours willing!

Hi Ken,
I believe the "loop feet" refers to bringing the ends close together to form a loop and measure the DC resistance, specified at 46 ohms per 1000 feet of wire. I guess that would be in each multistrand conductor. Been about 30 years since I was involved with that type testing.

32422. AW: [ham-antennas] Portable vertical HF antennas for RV, 18 ft or higher

Yahoo group: ham-antennas (2014)
Date: 2014-05-14 08:44:32 UTC
From: siegfried jackstien
Topic: 32395 Message: 32422

What about using a "mil-whip" ???

The lower sections of these whip antennas can be screwed together with as much height as you need ... one top section, one mid section and as much bottom section as you want (only one bottom section gives a quarterwave for 10m ... but you also can screw 18-20 feet of them together)

For nvis do not bend over the roof but backwards

Then you have a "low dipole" for nvis where the mobile home is one thicker leg and the whip is the other leg (been there done that)

For lower bands you can extend that whip with a wire (either to front of the RV or better to a treetop backwards from the RV)

I used such a setup years ago on my car (shorter whip while mobile and longer whip while on a parking lot) ... together with a yaesu autotuner

For mobile and working 80 and 160 I cut one of the bottom sections in halves and added a coil in between (so shorter whip on low bands could be used)

These whips are cheap ... and very strong (touching a tree would not hurt the antenna) ... and as explained above you can use any length .. with or without added coil ... and with or without added top-loading wire

The only tricky thing is to mount the base on your rv ... but you sure can homebrew something :-)

32423. AW: [ham-antennas] Will a loop give me a good signal?

Yahoo group: ham-antennas (2014)
Date: 2014-05-14 09:23:23 UTC
From: siegfried jackstien
Topic: 32409 Message: 32423

Build your loop ... you will love it

I use a fullsize topband loop here for all hambands ...

Yes on 160 it is a cloudburner (but not only 100 miles ... it gives you more) .... on topband I can work complete Europe ... that s way over 100 miles hi hi

And for 80m? ... between nvis and dx (depending on conditions a bit)

... no it will not outperform a vertical or a 4 square!!!

But it is a good compromise antenna...

From 40m upwards it is a real dx antenna (cloverleaf pattern with high gain) ....

an elmer once said ... if you can not make it high ... then make it long

AFTER I HAD MY FIRST 160m LOOP-ANTENNA I KNEW WHAT HE MEANT

Your quarterwave wire did not work cause you sure did not lay out a few dozen radials below it ...

If you have different options how to hang the loop (or where to feed the loop) ... then you should maybe simulate it in mmana and see where the lobes go on what band

I made my loop that way that I have highest gain on 40m in the direction with most distant dx locations ... from here it is vk/zl in direction south-west or north-east (short and long path)

But even if you do not pay attention on that and just hang it up the way where your trees are on the area ... (and it does not need to be exact triangle or square!) ... it will work "superb"

As an example ... my loop here is (seen from feeding point) one leg around 40m ... one leg around 60 ... and the opposite wire is around 70m

(no my loop is not 170 ... it is around 168 or so ... above are the rough numbers to show you that it does not need to be 56/56/56m)

.... build it ... and get on the air with it ...

And if you think that you also wanna work dx on 160 ... then it is time to ask the xyl for a radial-field ... grin ... and build a vertical or inverted L

In the file-area of this group you will find "loop.xls" ... that is an excel file that I made for my notes (testing resonance and swr on all bands with different lengths of ladderline)

And ... for building a vertical

Look for "folded monopole" ... it is a scaled down and modded (by me) vertical ... idea is from a local mw station (radio Bremen) ...

I would vote for the inverted L for 160 with 4 radials.

It wouldn't be too hard to dig just 4 in if that would please the xyl.

I put in a W8AMZ reduced sloper on my tower and have worked some DX from San Diego with it. However it is a very noisy antenna on receive and I had to homebrew a K9AY loop to hear any of the stations that I worked otherwise I have S9+15 noise versus S7 noise with the receiving loop. Just another possible option. The antenna is limited to 1KW if that is concern.

Ok. Don't radials need to be a quarter wavelength plus 5%? That would be something like 130 feet, right?

32427. 160M Inverted L (was 160 M Loop)

Yahoo group: ham-antennas (2014)
Date: 2014-05-14 14:25:03 UTC
From: Artek Manuals
Topic: 32427 Message: 32427

A couple of other tricks with the inverted L is to make it longer than required ...

I have built many L's for 160 which were in the neighborhood of 150' total length. The thought process is this raises the feed point impedance which for the L over a good ground is on the order of 15-25 ohms (higher over poor ground). By making the antenna longer than a 1/4 wave, the real portion R of the antenna impedance (R+jX) goes up there is a sweet spot where R=50 ohms. The problem is that with the longer antenna the jX portion also goes up. It is a simple matter however to cancel the added inductive reactance with a simple series cap. I use a 500PF vacuum variable with some hefty door knob ceramics in parallel to dial in the resonance point, this then gives a good 50 ohm match. and the variable cap allows me to tune the antenna very carefully so the 1:1 match is exactly at the frequency I want. All kinds of schemes here for switching in and out caps to allow you full coverage form 1.8MHz to 2.0 MHZ. Also the higher feed point might theoretically reduces the ground losses of a moderate radial installation. I say theoretically because I have never actually measured the differences.

The original poster on the loop thread spoke of using open wire feed which could be applied here as well. I don't personally like feeding an antenna like this with ladder line at ground level as I am not a fan of having ladder line laying on the ground. Also it is not inherently a balanced feed point. Also any loss improvement for open wire vs coax at this frequency is minimal. Theoretically you could feed the thing at any point by say breaking the vertical section say 20' up and attaching the open wire at this point while tying the bottom of the vertical directly to the ground system. Where it is fed makes no difference as I recall from modeling it several years back

Adding an 80M trap to the inverted L is also not an unreasonable project to make a dual band antenna out of it.

No in fact there was a detailed analysis in QST a few years back that suggested that ground radials slightly shorter than a 1/4 wave (.2 wavelength ? or about 100' on 160) were actually better for a ground mounted radials. Elevated/above ground (many feet) radials are another story and there 1/4 wave was better

Sigi,

Since no one has asked yet, where can you see, maybe get, one of these "mil-whip"?

32430. AW: [ham-antennas] Portable vertical HF antennas for RV, 18 ft or higher

Yahoo group: ham-antennas (2014)
Date: 2014-05-14 15:25:04 UTC
From: siegfried jackstien
Topic: 32395 Message: 32430

http://www.gelaendewagen.at/forum/viewtopic.php?f=3&t=7178

http://forums.qrz.com/showthread.php?260947-How-many-mast-sections-(MS-116-U-Type)-can-be-stacked-together

(scroll down a bit)

https://www.fairradio.com/_uploaded/740.jpg

(ms-116-a) the lowest element of the antenna set)

http://www.ebay.de/bhp/bw-antenne

http://www.helmut-singer.de/stock/-515580780.html

(singer sells surplus parts not only from military)

....

The antenna mast sections are copper clad steel ...

And lowest section can be screwed together nearly endless (I used up to 30 feet with guy ropes)

The fold-over spring is very strong ... you can bend that antenna over the roof ... and when you loosen the rope it flips up :-)

....

So you now have some sources (and you sure know how to use ebay/google)

http://www.ebay.de/itm/Antennenelemente-SEM-25-35-Funktechnik-MS-116-117-118-Ak-Bundeswehr-/261165409006?pt=NATO_Shop&hash=item3cceabe2ee

the lowest section is ms 116 ... mid is ms 117 and the top is 118

as far as I remember there was also another set available where all elements had the half lengths ... but I do not remember the numbers

Sure the us military has a similar antenna set for their jeeps

I used such a setup years ago on my car (shorter whip while mobile and longer whip while on a parking lot) ... together with a yaesu autotuner

For mobile and working 80 and 160 I cut one of the bottom sections in halves and added a coil in between (so shorter whip on low bands could be used)

These whips are cheap ... and very strong (touching a tree would not hurt the antenna) ... and as explained above you can use any length .. with or without added coil ... and with or without added top-loading wire

The only tricky thing is to mount the base on your rv ... but you sure can homebrew something :-)

CS:>> "You must be using this trailer for a mobile EOC ."

That's correct. We removed the bed from the master bedroom in front, and the two bunks from the bunkroom in back next to the head. The bunkroom is now the radio room and the master bedroom is an open area for general use. We mounted a length of angle metal to the back of the trailer along its full width and have mounted several VHF-FM and Airband-AM antennas on that.

As for the Eagle One, I like your method of tying a wire to the top and running it off horizontally, Inverted-L style. That actually sounds like it has the best chance of working in our application. A couple of questions...

1. You can partially extend that antenna, right?... rather than having to extend it to its full length every time. I can see instances where we would want to extend it to maybe 15 feet at the most, and run the horizontal wire from there to a convenient tree.

2. Does it look like there is a reasonably easy way to mount that antenna on the square bumper on the back of the trailer, rather than on the ladder? I guess the ladder will work but the ladder on that trailer just really looks marginal to me, to the point where at 250 lbs I really don't feel secure climbing it... maybe just a little paranoia on my part.

Ok. Don't radials need to be a quarter wavelength plus 5%? That would be something like 130 feet, right?

Be my guest with the partial raising of the antenna . There is only one restriction . The antenna is actually just a wire running inside the fibre glass support, so when not fully extended the excess wire is bunched up causing all kinds of problems. A simple fix is joints in the wire at select spots to remove the loops . I actually have traveled with my antenna only extended to the height of my AC units. I shorten the wire to length using connectors at the proper point to re-insert the full length when fully raised. Yes, while this tunes 10 meters easily it also listens to the truckers running down the interstates . After 35 years of Hamming I still listen in to that jargon that I never mastered . On your ladder , I would not worry . The load is not all that great with the antenna and even though in the industry your trailer is referenced to as " Stick & Tin " construction and as cheap as it was built it still had reinforcement behind the skin for the ladder. The frame will provide an adequate ground plane but a couple more are easily added . I use a couple 12" nails at the end of two 30' wires with an alligator clip to make the connection . They store easy.....just wrap the wire around the nail .....the nail is easy to shove into the ground and then retrieve. It is a fun antenna to play with.....I considered one for two years before purchasing . Chuck Wq5B

Radials do not need to be that long underneath the vertical antenna if it is ground mounted.

Best regards - Bry Carling

"Don't radials need to be a quarter wavelength plus 5%?"

ONLY if they are elevated radials! Sometimes called a counterpoise wire.

In or on the ground, the length more or less doesn't matter (well, it does somewhat, but it's different). What you read about quarter wavelength +5% does not apply to ground-mounted or buried radials. Putting the wires on/in the ground changes everything about them.

Andy

I thought I'd throw in my two cents...

I have a 102' doublet fed with 450 ohm window line, which works fine with a wide-range tuner from 80 m to 30 m. (It actually works on the higher bands, too, but I have a Yagi now.)

For 160, I short the two conductors of the window line and load it against six ground radials. I feed it with about five feet of coax directly to the tuner. It works fine. I put the ground radials about a half inch into the soil, and within a week you couldn't see where they were.

I'd do a long inverted-L or a loop if I had enough room, though.

I am looking for suggestions on a new antenna or two. Right now I have a G5RV mini up about 35 ft. I mainly operate on 20m and 10m right now but would love to start working 40m and 80m if possible. I rent so I am unable to do more than put up wire antennas in trees.

The lot I have to work with is 53ft wide with a tree in between causing a 23ft/30ft split in an E/W direction. Another option is 113ft with nothing in between heading in a NW/SE direction. The last option is 116ft with the same tree in the middle as the first configuration but this time causing a 46ft/70ft split in a SE/NW direction.

Thanks for the suggestions,
Justin

32440. Re: [ham-antennas] Antenna Suggestions

Yahoo group: ham-antennas (2014)
Date: 2014-05-15 02:53:23 UTC
From: Jim Bennett
Topic: 32438 Message: 32440

Justin,

I live in an area that the CC&R/HOA stuff says "no ham antennas", but that hasn't stopped me. I've been a ham for almost 50 years and the absolute best antenna I have ever had is the one I'm currently using for 40-6 meters: an 88 foot long doublet, center fed at 45 feet with 450 ohm ladder line. Both ends droop down a few feet, as my center supporting mast isn't exactly in the center. That ladder line runs to the outside of the shack, where I have a 4:1 current balun, and from there to my rig is RG-8X for about 10 feet. I have an Elecraft K3/KAT500/KPA500 for my rig, in addition to an Elecraft KX3. The tuners in the K3 and the KX3, along with the KAT500 tuner, have no trouble matching that antenna to 50 ohms. Using that doublet (and an Inverted L for 80 meters), I managed to accomplish Five Band Worked All States (5BWAS) in just under 3-1/2 years. And those years were divided between ham radio and active family life with two young kids.

There is nothing magical about the 88 foot length - it was just convenient. If you can up up a 90 foot doublet on that SE/NW heading, I think you'll have a great antenna system. You WILL need a balun, and you WILL need a tuner. But the antenna will work quite well - the higher, the better. I'm pretty confident that it'll also work on 80 meters. My 88-foot antenna loads OK on 80, but the Inverted L is a much better antenna for my situation.

Also, I'm using #26 "silky coat" wire from The Wireman in South Carolina - it is thin but almost invisible. No problem in those three years using this wire and up to 500 watts out.

Hope that helps, Jim / W6JHB
Folsom, CA

Hi,

Can I suggest an HF10 Western (see Eham reviews). It's a half size G5RV variant and works really well. I feed mine with twin feeder for even more efficiency.

Kind regards

Dave

32443. "New Balun" Failure

Yahoo group: ham-antennas (2014)
Date: 2014-05-15 17:02:12 UTC
From: p_chap@...
Topic: 32443 Message: 32443

A couple of days ago after finishing a few chores, retired to the shack for what was to be an hour or so of 40 meter QSO's on the 7410 before retiring to bed. I was greeted with about the right noise and signal strength on the band. However due to the pulsating buzz type noise and badly distorted receive audio, It turned into a troubleshooting evening. Changed antennas, went to 20 meters, all is good. Switched the 40 mtr antenna (double bazooka) to the Icom 718, got the same pulsing buzz and audio distortion. Put the analyzer on the antenna, SWR up to about 1.2 : 1 up about 1 point. Still, I figured the antenna was somehow fried from the windy storm the previous night. Dark and late.....check it tomorrow I figured. When I got home the next day, climbed up on the roof to find the feedline had made four nice compact wraps around the Arrow 144/440 JPole. (physically three vertical rods screwed into a base mounted on a plumbing roof stack) I unraveled my new balun, and all is well again. I also ran other measurements with the AA-54 and will compare to what normal really is.

When things like that happen, it makes me very happy I spent the bucks on setting up the three Alpha Delta console type coax switches. It takes the pain out of troubleshooting.

Paul,
WA4NUN

Ross,
Regarding your leader:

"A fast easy way to install the ground radials without any digging or trenching see:"

<http://rossradio.net/> http://rossradio.net

There is a myriad of information here, way to much to wade thru in one sitting. Where is the specific reference a "fast way to install...without digging or trenching"?

Ray, W4BYG

"The Republic (America), can survive a fool like Barack Obama, who is after all, merely a fool. It is less likely to survive a multitude of fools, such as those who made him their president." Vaclav Klaus, Former Premier Czech Republic

> Because the loop is basically a horizontally polarized antenna at 40' it will be cloud burner. A better choice for working WAS and some DX from 4 land would be an inverted L. Sounds like you have a decent sized yard so maybe even two inverted L's fed in phase switchable broadside and end-fire. With a 45' high inverted L, I owrked 68 countries on 160M the first winter I put it up and that from what is known as the "black hole" (upper midwest) for 160 M. The other part of making the L work is ground radials at least 16 ..more than 50 is not worth the effort. An amp for 160 is also advantages more so than any other band...

32446. Re: Antenna Suggestions

Yahoo group: ham-antennas (2014)
Date: 2014-05-15 21:32:00 UTC
From: kd2bhm@...
Topic: 32438 Message: 32446

Jim,

Thanks for the suggestion. Does the ladder line need to be a certain length? I just moved from an HOA and the only thing I could fit was this inverted V G5RV mini that is only about 45ft long. I have a LDG AT200ProII so that should be able to tame things. Thanks again for the suggestion.

Thanks and 73,
Justin K2SAF

---In ham-antennas@yahoogroups.com, <w6jhb@...> wrote :

Justin,

I live in an area that the CC&R/HOA stuff says "no ham antennas", but that hasn't stopped me. I've been a ham for almost 50 years and the absolute best antenna I have ever had is the one I'm currently using for 40-6 meters: an 88 foot long doublet, center fed at 45 feet with 450 ohm ladder line. Both ends droop down a few feet, as my center supporting mast isn't exactly in the center. That ladder line runs to the outside of the shack, where I have a 4:1 current balun, and from there to my rig is RG-8X for about 10 feet. I have an Elecraft K3/KAT500/KPA500 for my rig, in addition to an Elecraft KX3. The tuners in the K3 and the KX3, along with the KAT500 tuner, have no trouble matching that antenna to 50 ohms. Using that doublet (and an Inverted L for 80 meters), I managed to accomplish Five Band Worked All States (5BWAS) in just under 3-1/2 years. And those years were divided between ham radio and active family life with two young kids.

There is nothing magical about the 88 foot length - it was just convenient. If you can up up a 90 foot doublet on that SE/NW heading, I think you'll have a great antenna system. You WILL need a balun, and you WILL need a tuner. But the antenna will work quite well - the higher, the better. I'm pretty confident that it'll also work on 80 meters. My 88-foot antenna loads OK on 80, but the Inverted L is a much better antenna for my situation.

Also, I'm using #26 "silky coat" wire from The Wireman in South Carolina - it is thin but almost invisible. No problem in those three years using this wire and up to 500 watts out.

Hope that helps, Jim / W6JHB
Folsom, CA

Justin,

Just about any length will do. As I mentioned, a 4:1 or 1:1 current balun between COAX and ladder line is essential. Run the ladder line a minimum of 6" away from any metallic objects, like rain gutters, metal buildings, etc. That LDG tuner ought to be fine.

32449. Mobile Screwdriver Antenna wont tune 20m suddenly

Yahoo group: ham-antennas (2014)
Date: 2014-05-16 02:07:06 UTC
From: Goldtr8 (KD8NNU)
Topic: 32449 Message: 32449

Hi Guys,

I just installed a new screwdriver antenna on my Ram pickup this weekend and it was working really good until today. It tuned up I did some bonding and I was happy and going to work on finer details for just making it a better installation.

The problem is that it will not tune 20m band anymore as of today. I have tried different coax, different whip lengths with and without a matching coil and it won't tune in for that band. Plus it tuned 10m just fine on Sunday but today it is not short enough for that band either.

Its been raining non-stop since Monday and I am thinking that its moisture inside the antenna or connections. But I am really clueless.

I called gent who makes the antenna and he thought water in the coax but I put a short section directly at the antenna and still same problem.

So anyone have ideas you can kick over to me to look for I am really stumped. I never had any issues on the old antenna with the Jeep so this is really got me clue less.

Thanks
Don

Don

If you have eliminated the coax...then it is possible that screwdriver antenna coil is wet espcially if you were running it up and down in the rain. Take the antenna off and place it under some heat lamps for the night to try and dry it out. Blow it out with compressed air etc

Once you have convinced your self that the coil is REALLY DRY and it is still not tuning then the next suspect (though unlikely) is the bonding changed the ground plane characteristics. Remove the bonding and see if it returns to life that way. When you said you "did some bonding" give more precise details

Add RF earth strap to chassis from close to aerial base in Mount.?
I use flattened braid from RG8 coax.

<<After 35 years of Hamming I still listen in to that jargon that I never mastered . >>

HAHAHA!!! I do too! When the DX is slow, I will go to 27.025 (Channel 6) and listen to the big boys duke it out! What a show! I was listening on my FT-950 the other day, and heard a guy calling himself "Painkiller" just blanking everybody with a s-9 + 20 over signal. Now, somebody with a signal like that on AM? Must have a big light bill! 'Course, listening to 27.025 can give you an idea of propagation without having to chase down beacons on 10 meters!

I got lost when "Good Buddy" got to mean something else, and they started calling everybody "driver". Only talked on that band a few times, and then got a Ham ticket. Never looked back.

Since most of the aluminum tubing used in the world has nothing to do with ham radio, by Googling "aluminum tubing suppliers" you'll turn up dozens of suppliers, a good number of which specialize in small-quantity orders. UPS will ship up to 105" lengths. DX and other ham suppliers use truck shipping to longer lengths. So do the ones you'll find using Google.

Here are a few excellent examples:

http://www.speedymetals.com/c-8371-round-tube.aspx

http://www.onlinemetals.com/merchant.cfm?sortby=od&step=2&id=71&showunits=inches

https://www.metalsdepot.com/products/alum2.phtml?page=rndtube&LimAcc=%20&aident=

Yes, I have one of those. I was in a hurry, so bought one
(MFJ-1777<http://www.mfjenterprises.com/Product.php?productid=MFJ-1777>),
but I have built several. You can also cut one for 40. It becomes a double
Zepp on 20 (1.9 dB
over a dipole), an extended double Zepp on 15 (2.3 or so dB) and is very
effective and directional. I am going to convert my 20 meter dipole to one
of those, removing the coax and replacing it with balanced line. A better
name would be "multi-band", as the one shown will not work on 160 without
some fiddling.

Friendly correction: it's Alan Steel, not Allen Steel. Here's a web site with reviews:

http://www.yelp.com/biz/alan-steel-and-supply-redwood-city

If you live in the vicinity of Medford, Oregon, there's also White City Metals:

http://www.whitecitymetalssupplyor.com/
http://www.yelp.com/biz/white-city-metals-and-supply-white-city

That's where I get my stuff. It's only three miles from my QTH.

Hi,

I always used a motorcycle boot on the coil for the rain and bug spatter problem. On the bonding, you can go to a NAPA auto store and buy any length of battery strap braid you want.

From: crrestoration@...
Topic: 32464 Message: 32464

Hi all,

I have an AV-18AVQII vertical that is ground mounted (HOA)
in the corner of my small yard.

I am using this for phone with my Kenwood 440sat.

Problem is I cannot hear anything except occassionaly at certain times/frequencies during the "grey line" morning or evening.

Not that I follow W1AW but have never heard but a faint CQ from any of them.

I have an analyser and have matched the bands to the lowest SWR with new RG8X coax.

I have installed half a dozen radials as long as possible.

Any suggestions will be welcomed,

Regards,
Chris

That seems rather odd: what bands are you talking about?

Chris,

Have you checked the coil at the bottom of the antenna? I have a an AV18 ground mounted, with no radials, and I pick up plenty. Can we compare it to a 100’ tower with a beam? No but with HOA’s in place what else can we do. I think the problem might be around the coil at the bottom, the clip or the wire going from the coax to the clip. I had this same problem with a “hidden in a tree Jpole for 2 meter/440” and I switched out the coax with a new one and that worked. But I see that you tried that so I would suggest either the coil, or where the coax connects to the coil. Good Luck

John,

The newer AV18QII no longer has the loading coil at the bottom of the antenna.
(I'm thinking this is what you meant).
I'll take it down and look it over to make sure everything looks ok.

Thanks,
Chris

I would first test the antenna without the feedline putting the
analyzer as directly as possible at the feed point of the antenna to see
if the feedline is effecting things. (feedline disconnected)

Any large metal object near the antenna will mess it up, such as a
chain link fence.

You don't say where you live, but W1AW on 40 meters comes in about 10
- 20 over S9 in West central Florida and should put a good signal into
most of continental America, WWV on 2.5, 5, 10, 15, and 20 MHz should
put a good signal into your location in the evening or nights on one or
more of these frequencies just about every day, the higher frequencies
drop out as the MUF lowers during the evening except for when we are at
the peak of the sun's spot cycle.

HOA or not your allowed to live there and make small temporary
experiments . Take a coax (old or new) with only a connector on
the radio end .....to the other end attach two wires
one to the center conductor the other to the shield . Do not worry about
lengths. Connect to the reciever and listen to all bands once again
.....feeling brave ? apply the tuner to a reasonable band
listen again. Do you hear anything ? You now know if you have an
antenna problem or you live in a Black Hole where no RF has gone before.
Now attack the obvious or advise the results for further
assistance . Chuck Wq5B

Hmmmm....sounds to me as though you have a shorted or open coax of "just the right length"....but you changed that once, as I recall.

Something ain't making contact somewhere, that's for sure. Or your receiver is defective.

Even on a piece of wet string (well...almost), I get WWV and W1AW loud and clear here in Northern Idaho.

A 4 foot long piece of wire on one of my WWII ARC-5 receivers does it from 2.5 MHz up through 40 meters, even inside the shack.

Someone suggested that you take a hunk of coax with a fitting on one end, connect two wires to the other end, one to shield and one to center, connect THAT to your receiver and see what you hear. Even lying on the ground, you should hear plenty of signals.

I agree with that.

Hang it on the fence, and it would double your signal strength.

Oh. One more thing: try to unscrew JUST the ground connection of your coax, leaving the center conductor connected to the receiver but making certain the shield is NOT connected to anything at all, and see if you hear anything then.

Maybe there is a problem with your receiver?

Topic: 32472 Message: 32472

Hi - I'm getting ready to build a 30 meter vertical, using aluminum tubing sections. I built a model of it in EZNEC and the results are pretty much in line with what I have seen in the ARRL Antenna Book and other publications regarding verticals - their impedance is around 28 - 35 ohms. Obviously, after I build the vertical I'll put my AIM4170 on it and see exactly what the "real" world reading is.

If it comes out to be what was modeled, I was thinking maybe I'd build an Un-Un to match it to my RG-8 coax. I realize that the tuner in my K3 and the KAT500 can easily match the vertical's impedance to 50 ohms, but in the interest of experimentation, I thought about the Un-Un. Jerry Sevick's (SK) book on them shows one that is a 1.56:1 ratio, or 50:32 ohms, which is pretty darn close. He used a 1.5 inch OD ferrite core with a permeability of 250. Anyone know where such an animal can be obtained? What about higher permeability cores, like mix 43, having a permeability of 800 or more?

You can raise the feed point and droop the radials to get a 50 ohm match. I did this with a 40M vertical and a wooden mast.

Rich, I can't raise the feed point. The vertical is pretty much in the middle of the back yard, ground-mounted, and my radials are covered up by the grass. So my choices are (1) build a un-un that matches 50 ohms to 37 ohms, or (2) just foggedaboutit and let the K3 or KAT500 tuner do the matching. I'd sooner go with number one, but my quandary is what mix ferrite to use. Sevick's book doesn't mention that little tidbit (unless I missed it somewhere), and there are a gazillion different mixes. I'd like to get a ferrite core with an OD of about 1.5 inches and a permeability around 250.

Jim I threw together a portable antenna based on WB3GCK "Pop-Up Vertical 2".
< http://www.qsl.net/wb3gck/puv2.htm >
I would think that the same T200-2 core would work for your application.
I was going to order mine through Amidon but there minimum order is $20
and I didn't need that many Cores.
So I purchased mine off of Ebay by searching for T200-2.

The T200-2 is an Iron Powder Core and 2 inch OD.

If you really want that 1.5 inch OD then take a look at <

Several other ways possible

One way is ... ground the base of the antenna and use a gamma match

(would also give additional lightning safety and a way for static loadings to ground)

Now you can easy search the 50 ohms spot at the base

.....

Next option would be to make the antenna slightly longer (to lift up impedance) and use a series cap

....

Third option is drop the radials at 135 degree downwards and lift the feeding point over he ground

....

I do not like transformers at the base of a vertical if I can use other things

On ur problem not tuning 20m, have you changed anything or added thing near the mounted antenna?

On the cover for the coil, I looked and looked for years for different material to cover the coil.
I have used plastic Whiffle bats. I made 3 different size antennas 2", 1.5" and 1.25" all copper pipe.
Used the Un-Un for matching don't recall having luck shunt feeding. Later on I found pvc pipe which was I believe called SDR by one manufacturer THIN walled not easy to find in all sizes I had to go direct to the manufacturer in Michigan and most sizes were available there. Can't remember the name of the town but was some where near Flint Michigan, 60 miles or so north of my location.

Hi Rodney ☐ I am using a Bazooka made from RG-213 and then I installed 4 inch diameter wire cages on the ends at approximately 20 feet long each ☐ I like it ☐ overall it is fairly heavy and the band width isn☐t necessarily any greater than a standard bazooka ☐ it simply performs well

I have a Lil Tarheel II mounted on my Ram pickup. I was having problems tuning 20 and 15 meters, really all the higher bands.I made some changes in the grounding and now all bands tone to 1.5.1 or better EXCEPT
20 meters which I can now get to 2.1, it was way over 3 but I have been playing with the length of coax and the swr has improved. I thought I needed a shunt coil but 80 and 40 tune perfectly so I was told I don't need a shunt coil. I am using an IC-7000 and have the Better RF controller that I was unable to use because of not being able to tune some bands. I hope to be able to hook that back up soon. Good Luck!

Ken,

I also disconnected the coax half way from the radio and all I get is S4 static with an almost impossible to hear signal from WWV.

I made a coax fed dipole? of 66' which should be able to get something in the 40 meter band as far as I know. I could hear a very faint net around noon today.

I was able to hear WWV 10MHz at about an S5 on my Hy-Gain but about an S4 on the dipole.

I could also hear it about an S2 on my dummy load.

I tried all the frequencies (phone) for W1AW listed on dxforme an both antennas and never heard a thing.

I am in the SF East Bay area just for info.

At this point, I would suspect your RECEIVER...

Borrow another rig from someone near you, hook it up and see if there is a
difference. I'll bet there is.

I too suspect your receiver.....at this point you
have two options .....one: repair your receiver or
two: all that studing was to transmit and many consider it more fun than
receiving , you could just CQ until you locate a signal strong enough to
hear . Check your attenuator and RF gain control before going any
further Chuck Wq5B

W1AW is on land that was chosen because a 40 meter rhombic antenna
pointed at California would produce a usable signal all year round in
California, it was later discovered that a 3 element beam was just as
effective. (with much less feedline)
There is no excuse for not being able to hear W1AW on 40 meters in
California. (or Florida)

If your receiver has a "pre-amp bypass switch" of any form what does
switching back and fourth do to the sound level and "S" meter reading
while listening to a signal of some strength?

Ron,

IF-shift checked and and adjusted when neccesary.
I had a 500+ mile qso last night on 40 with a 10 over report.
The problem is that I could not hear 1/4 of what he was saying.
So it seems that tx might be ok? and just a problem with rx?

Thanks,
Chris

The laws of reciprocity hold meaning that if the antenna works on Xmit ,
it works equally on receive.

The problem is either with your receiver or your ears (no offense
intended just had my done ...if you have not priced hearing aides be
prepared for sticker shock)

Dave posted the correct response: reciprocity.

Obviously, now, your antenna is not at fault and can now be completely eliminated from consideration of the problem.

I repeat: the problem is in the receiver....either the electronic one or the human one.

To eliminate another variable, borrow a WORKING rig, with a working speaker, connect it up, and see what you can hear.

If you still cannot hear anything, have your hearing checked immediately.

Unless the desert is in the SF bay area there has to be a ton of HAMS
within 50 miles of you, google "HAM club in [near by city]" until you
find one. Join it, attend meetings, make friends.
I was shocked to find that the 16,000 person town that I live in has
over a hundred HAMs living here. (20 years ago)

OK. Then the problem is obviously your radio.

> I do not know anyone that does the radio thing so borrowing one is out.

Heck, there must be at least 50 hams within throwing distance of you. What's your call and location? I'll look a few up for you...

> As far as I know the closest radio repair person/shop is over 500 miles away.

I would very seriously doubt that, but in any case, that radio is WELL worth fixing and keepiing and operating, even if you have to pack it (properly) and ship it. Isn't it a Kenwood TS-440?

> I
> guess its time to save for something newer as this is 35+ years old. Chris

Ha! I'm 72 years old and not ready to be put to pasture yet.

And every piece of equipment I own is at least 35 years old, and it all works just fine. Some of the best receivers I own are 70 years old, and one of my favorites, an ex-military RAL-7, was designed in the 1930s.

Just 'cause its old, doesn't mean its worthless.

Realize that by now all the bad ones have "gone away" and those that are left are usually pretty good.

Ken, Chuck, Ron,

I looked up a map of licensed hams in my area and it looks like one every block.
I never hear any of them, except for 1 guy who causes trouble on 40 and 80.

I guess I can ask the guys down at HRO in Oakland if they know anyone who can look it over.

Last year I could not track down a tx problem so I purchased a used tx board and it fixed that.

The radio (Kenwood TS-440/sat) looks almost new, Last year I also installed the bhi dsp unit.

I really wish I could compare it with something newer to see if I am really missing out on the newer technology.

Anyway, Thanks all

Chris

About the only thing that is new would be digital noise reduction and
bandwidth limiting, digital heterodyne suppression and digital modes
that change to added connectors and memories, these simply add conveniences.
What you have (once repaired) will thrill you if you give it a chance.

Not unusual. Most will not be active. One or two will be, but will keep a
low profile.

> I never hear any of them,except for 1 guy who causes trouble on 40 and
> 80.

What sort of trouble?

> I guess I can ask the guys down at HRO in Oakland if they know anyone who
> can look it over.

That might be a good idea. I know there is at least one other fellow who
specializes on those rigs. I'll try to dig him out. A K4 as I remember
it, in Flordia

At this point, I would not recommend Land-Air-Communications, though,
mainly because I have zero experience with his operation.

Clif at Avvid does TS-440s. He is a real expert, honest, hardworking and
reasonably fast. His work is top notch and his rates are reasonable.

You can look him up at http://www.avvid.com/, get his telephone number
from the website and give him a call to discuss your rig.

As Ron pointed out, there isn't really much in the newer rigs that would
make a real difference in operation. For one thing, many of them have a
stack of menus that can be overwhelming for many people.

Your TS-440, once repaired, is an excellent and very reliable rig.

Not easy to calculate that length

Needed end depends on how much loading the trap adds on 160

If you have a big coil and a small cap or a smaller coil with a bigger cap

The resonance of that cap on 80m would be that same but the loading on 160m would be different (more l ... lower length needed)

Only way I would guess is ... add a few metres (with some test wire of your junk yard)

Measure resonance on 160

And then make "stinger" longer or shorter depending on where antenna resonates

Yes it can be calculated ... but it is not easy (maybe simulating with mmana would work) ...

So best is ... try it out :-)

>
> The resonance of that cap on 80m would be that same but the loading on 160m
> would be different (more l ... lower length needed)

With some persistance, there may be an ideal combination of L and C that
might possibly bring a third band into play. Might!

> Only way I would guess is ... add a few metres (with some test wire of your
> junk yard)
>
> Measure resonance on 160
>
> And then make "stinger" longer or shorter depending on where antenna

> Yes it can be calculated ... but it is not easy (maybe simulating with mmana
> would work) ...

Oh, it's not too hard if you know the C or L of the trap, having made
the trap, perhaps one knows one or the other, depending how it is made.
(And maybe the Q of the trap, but for approximate work, Q = 10 or Q =
100 or Q = 0 will work.) Then given C or L and the fact of resonance
at 80m, you know the other. Then calculate X(trap) at 160m. Two X's
in parallel, eh?

The problem is then one of calculated the X of the trap at 160m. And two
other things: the self-inductance of the 80m section of an arm and the
self-inductance of an *untrapped* 160m arm. In other words, you want
the completed trapped antenna to have the same reactance as an untrapped
160m antenna **on 160 m**.

Then
X(untrapped 160) = X(80 section) + X(trap) + X(unknown)

Solved
X(unknown) = X(untrapped 160) - X(80 section) - X(trap)

where all the X calculations are performed at 160m.

This is definitely within the scope of the US Amateur Extra exam, using no math beyond secondary school. (Actually no math beyond simple arithmetic.)

What I'm not giving is the formula for the self-inductance of a solid copper wire. Heh. Let's leave something for the student and for Professor Google to do.

The foregoing is an *approximation*. I am ignoring resistance and the self-capacitance of a wire. Actually I assumed that the Rs are negligibly different in the trapped vs untrapped calculations. I think this is safe.

> So best is ... try it out :-)

The preceeding notwithstanding, I tend to agree. Since the antenna will doubtless be used close to ground, capacitance between antenna and ground is going to be (probably) a bigger issue than my simplifying assumptions above. So, measure long, cut short!

An antenna analyzer like the ubiquitous MF-259B ought to be able to measure the X's above, too, as far as that goes. The clever student will keep in mind the sign of X, which is negative for capacitors.

I have a similar problem at my QTH . using a triband dipole 10,20 and 40 metres , I get good reports on transmitted signal using FT950 . however I have problems hearing all except the strongest signals . I took the rig and antenna out to a friends place about 25 miles from the city and set it up using the jeep as the power supply and could hear everything with no problem . I suspect the poor reception is just my location . I have a
S9 to 20 over noise level most of the time and I have powered the 950 with a battery and shut off the mains and still have the noise . if you can take your setup to a different location , like a park or somewhere and test it there before sending it for repair .

good luck

Chris,

I have been reading the responses and following this thread since my last answer. I did not know that the antenna had been remade. I would also agree with others about reciprocity regarding if you can transmit, then you should be able to hear them. I think a problem might be either in your location (which cannot be changed) or in something producing some form of electromagnetic radiation, which you cannot obviously hear, yet it is interfering with your reception. I would start doing some tracking with a portable battery operated receiver, just to see what you can see. I have the same radio, a Kenwood 440S/AT and would not give it up for anything, and would say you should not give yours up either. This is a good radio and mine has performed admirably both in ham service as well as AFMARS service. Just my $0.02 worth.

Chris,

Another thought. Have tried on the 440 group here in the Yahoo groups? ts-440-subscribe@yahoogroups.com is the link. But rather then follow the licks, I do a search in the Yahoo groups. I do know there are a few hams in the group that repair the venerable 440. I start seeking ideas and fixes and people there.

About the only thing that is new would be digital noise reduction and bandwidth limiting, digital heterodyne suppression and digital modes that change to added connectors and memories, these simply add conveniences. What you have (once repaired) will thrill you if you give it a chance.

Another thought is that there could still be something wrong with the transmission line or antenna (the antenna system). Just because you can be heard when you transmit does not mean the antenna system is working properly. You might be putting 100W into the transmission line, for example, and only radiating a watt or two due to antenna system issues - enough to be heard (QRP'ers do it all the time) but also enough issues to greatly attenuate received signals.

I suggest you not exclude the possibility of antenna system issues until you determine the source of the problem. Given that the radio worked fine at another location, I would check and verify EVERYTHING in the antenna system starting at the antenna jack at the rear of the radio on out to the antenna. This includes any external tuners, baluns, inline chokes, coax or other transmission line, and the antenna itself. It could be a poor connection, poor coax (my suspicion), etc., or a combination of issues in the system that greatly attenuate both tx and rx signals. It all needs to be checked out.

Just a quick suggestion...You said you had installed a BHI DSP unit last year, IIRC. Make sure you have it turned OFF!!! If it's cranked up too much it can really cause problems with the reception! You could also have a front end problem caused by temporary overload, ie:a nearby lightning strike, but I don't think you have too many thunderstorms in your neck of the woods. Turn off the DSP and see what changes take place. (sorry for the slow response, just catching up on my 300 emails! Good luck, 73 de Ron...n3tlq

If it is only one or two noise sources (defective isolator on power pole or a switching psu from a neighbours sat receiver or similar) ... then it should be possible to find the noise source ...

But if you live in a big city with thousands of such noisy things ... then I wish you a good luck to find them all

Hi Sigi,

You don't have to find them here in the USA,
Once you can confirm it is Power Lines you file a complaint (Maybe up to 5 times) with the power company in the local area and they have to find and eliminate the interference.

I once filed a complaint with Southern California Edison due to TV interference with channels 2 to 6 in LA area.

They were not happy but they had to replace 13 miles
of insulators and wiring to stop the problem as it was in a direct line
from my house starting across the street to the TV towers!

YOU do not have to find it all.

Thanks for the ideas .
La Grange is not a large city and I have walked around a 6 block area with a Grundig mini 300 and found noise at every pole and transformer I checked . I did find one arcing arrestor on a transformer in the next block . I had walked over to a neighbors house and heard it , getting louder the closer I got to it . I live in a semi industrial area so it could be anything . gave up looking for it and just deal with it as best I can . there is also a leak in the cable system that is interfering with the local repeater to the point where no one uses it any more . It is the audio from TLC . reported it to the cable supplier and they were not really interested in repairing it . A new company owns it now so maybe something will be done .

If I remember right you have a RIGHT to clean reception (freedom of information) ... so if you have many noise sources you should moan as loud as you can ... to the power company ... to your neighbour ... to the cable company

Power company sometimes are thankful for such reports (if they do NOT have to replace 20 miles of insulators hi hi) ... reason is ... they loose power on defective insulators (some amps here and some amps there) ... I am guessing that you can power a major city with just the LOSSES these power companies have on their defective insulators and transformers

With your grundig you find noise on every pole yes ... but did you also look if it is not just rf coupling from the lines to your receiver??

If there is a big defect on the insulator it makes noise up to vhf/uhf (sometimes changing with weather conditions)

And then you can use a small yagi to track down the noise source

Good luck in getting a better receive

(last option would be ... MOVE AWAY)

When it comes to the cable company, use the FCC. They are slow....but they will take action. You could also feed the report to the ARRL for them to push for help.

An arcing lightning arrestor is costing them a bunch of power. If you report that, it SHOULD get replaced. Give them the location.

In Tampa, I watched one lightning arrestor blow up from the fourth floor of a bank. Even behind triple pane windows it was deafening from 2 blocks away. (If they get hot enough they go boom... that one had taken its limit on lightning strikes..)

The arcing probably is coupling to the distribution lines, spreading the noise...making it appear at every pole...

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

A group I know had a problem with Cable leakage getting into the Repeater
Input. The Cable Company was not interested in their problem.

The solution was to hold a Simplex Net, nightly, on that frequency. The
start
time was 8PM (Prime Time !!).

The leakage problem got cured rather quickly.

Andrew,

No matter if it is a small town or big metropolis, it is required, by law (unfortunately I don□t remember the citation for the legal stuff) to repair it if any interference is reported. If they refuse or take a □it doesn□t matter□ attitude, then go up the food chain, til you get to the Board of Directors of Fayette Electric Coop. I know that in a small town I used to live in, if you made a concern known to an administrative assistant, and nothing was done within 3-5 days, then you could go up to a director then up to a member of the board, and they would take it seriously. Remember, as a coop member, you are one of the owners of the company, and you have rights as an amateur operator as well. If this complaint process doesn□t resolve the matter, then contact the ARRL and ask for a local attorney to help. However, I can bet that if you have to go to a member of the board, it will get solved before you have to go to the ARRL. One important point: KEEP RECORDS!!! DILIGENT AND DETAILED RECORDS!!!! This is important going forward, as you can show what you have done, who you have contacted, and what they said or did to assist in solving the problem, (or what they refused to do).

Just my opinion.

Hello All,

Set-up= FT857D/LDG200Pro and a doublet antenna cut for 160m-6m, the ladder line is 450 and is about 150' maybe 160', I also have a 4:1 Balun with about 20' of RG8U coax. My QTH is 849' ABS and my Doublet is 65' ABG. I was doing equipment check today to make sure that everything was in working conditions.

To give you you more information about my antenna:

It is a doublet with 260' from north to south and 130' east to west this is respectful to lobes. So in it's simplest form it is a fan doublet with 160m and 80m at the feed point and the two closes angles of the wires is about 35 degrees, the others are about 45 degrees or more.

As I checked the radio everything was fine into the dummy load. After that I checked the tuner and everything was fine into the dummy load after the tuner. Once I connected the antenna things went a little different then I hoped. I disconnected the antena and brought out the old trusty MFJ-259 (non B) and the antenna SWR was high on the higher bands and it was low on the lower bands. 30 meters or higher the SWR was above 3:1 or higher but, the resistance was below 75 ohms. 40 meters and below the SWR was less than 2.9:1 and the resistance was below 75 ohms. On the SO239 side of the balun of the doublet I took a regular voltmeter and made sure I had my zero ohms. Yes I did have the zero ohms.

Now I am at the point of where do I go from here and what would be my next step?

I do not know what other information is needed for the Elmering that I am in need of. I really do not want to take this antenna down from its 4 support points. Unless I really and truly have to.

If anyone has any idea(s) that will help will greatly be appreciated. Thank you in advance for all the Elmering of those in this group.

KD8DVY/QRP

Harold,

Just a quick thing I take it both lengths of the dipole dublet are the same size? Also have you tried the 4:1 balun straight at the back of the ldg tuner and the ladder line straight into the balun doing away with the 50ohm coax

Cutting a two band fan dipole for 160-6 meters strongly depends on
having a very wide range tuner and I believe most would use a "T" type
of tuner. What make and model tuner are you using?
Lacking that, you can add lump constant reactances (or preset lengths
of added feedline) for particular bands. You are fortunate to have the
room for such a large antenna.
Another alternative is to erect another antenna, perhaps for 20
meters and use it with the tuner for the higher bands.
(perhaps with coaxial feed)

The set up you describe will give SWR's of 3:1 and higher on all bands
40 meters and above by design. This is because each leg is a multiple of
1/2 wavelength (with the exception of the WARC bands)

Regardless of the statement above, baluns are always suspect until
proven other wise. I personally "characterize" any balun home brew or
commercial over the frequency range of use. In this case since it is a
4:1 I would terminate it with a 200 ohm resistor and then check the to
be sure it is reading 50 ohms (1:1 SWR) across all frequencies you
intend to use it.

Assuming the balun is good, the losses due to SWR will be minimal with
the ladder line and only 20' of coax. Since you say you have an antenna
tuner, as long as the tuner will match the the the antenna feedline to
the transmitter with 1:1 SWR I would not worry a lot about it.

A final bit of wisdom ..Given the history of quality and reliability
problems with MFJ products I would leery of making judgements based
solely on data derived from that unit

I am going to go against what Randy, and many others say here regarding the Zero-Five. I would personally not trust ANY company who tries to tell me that they have overcome the rules of radio transmission and that their antenna is so superior it does not require radials. To my knowledge all commercial radio stations invest a substantial amount in their antenna's and grounding. Would they do so if they didn't have to?

EVERY antenna requires a ground plane as it makes up half the antenna. Think of a dipole with both legs, of equal length. When coax is attached, the centre core goes to one side of a dipole and the shielding/ground going to the other leg i.e. One to the ground and the other is the driven element.

I too am looking at an HF antenna having obtained an HF rig. Unfortunately I am space limited although I could possibly fit a half size G5RV just above my house roof. Unfortunately I won't be able to work 3.5/ 80m and 1.8 MHz /160m but 40,20, 10m plus a Slimjim for 70cm and a separate vertical for 2m should be OK, at least to start. Hopefully I will find a homebrew way by possibly combining two G5RV antenna's to work 80 and 160m.

My 2c's worth from South Africa and thanks for starting the discussion.

For the power,line problems complain to the local power company a few times preferably to an upper level supervisor, each time you call *fight to get the next higher supervisor!*

For the Cable problem file a complaint with the FCC field office for your area if no satisfaction with one call to the *Manager* of the cable company.

If no results from power company after about 5 calls (About 1 a month) then also report to FCC Field office.

If it is making a local repeater unusable then chances are very good it is interfering with local emergency and air traffic to some degree as they are all in about the same Freq spectrum.

Hope this helps.

Remember the *"Squeaky wheel gets the grease!"*

Just to update the group.

My problem appeared to be water in the N connector adaptor. After drying it out and filling all Coax connections with STUF the problem has gone away and not returned.

I also rebonded everything using start washers and an anti-corrosion grease for extra measure. The antenna now tunes all bands from 80 to 10 no issues.

Thanks for everyone who sent me things to try.

Subject: [ham-antennas] Re: Mobile Screwdriver Antenna wont tune 20m suddenly

I have a Lil Tarheel II mounted on my Ram pickup. I was having problems tuning 20 and 15 meters, really all the higher bands.I made some changes in the grounding and now all bands tone to 1.5.1 or better EXCEPT
20 meters which I can now get to 2.1, it was way over 3 but I have been playing with the length of coax and the swr has improved. I thought I needed a shunt coil but 80 and 40 tune perfectly so I was told I don't need a shunt coil. I am using an IC-7000 and have the Better RF controller that I was unable to use because of not being able to tune some bands. I hope to be able to hook that back up soon. Good Luck!

Here is a new one for you; Bought a safety belt at Dayton so I would not have to borrow someone else when I needed to go up the tower. I have the old Standard (a fore runner of Rohn) tower which uses the "X" crossbars instead of the common Rohn which uses the "Z" pattern. About half way up, the snap "snapped" firmly in place. I did not realize that as the tower got higher the crossbars got smaller, and that "snap" I heard, was the sound of the clamp making a very firm grasp of the crossbar because they were almost identical in size and, in which I could not get to release. I saw my neighbor come home from golfing but could not get the courage to shout at him, and I knew my wife could not hear me. The only visions I had was the local fire department with their boom truck in my back yard. After "dangling" up there for about 15 minutes (which ed seemed like an hour), and sweating up a storm, I finally got it to release and decied that was as high as I was going up tonight, and until I find a work around.

The *smoke test* is just to hook it up to your rig, give it a try, and if it or your rig doesn't smoke, it passes.

Actually, you'd probably want to hook an *SWR meter* between the radio and the antenna, set you rig to no more than 5 watts (less if possible), and take different readings up and down the band. If you can get it up on some kind of temporary mast--even just ten feet up, that'll give you better readings. Try to test it away from big hunks of metal if you can, and use 20ft or so of coax so you can get a little ways from the antenna to minimize the effect of *body capacitance*. All this would be for just a preliminary test. The readings will be a little different in its permanent location.

Better still would be an *antenna analyzer* for testing. If the *SWR* is less than 2:1 (at least somewhere in the band), give it was try. Point it at one of your local repeaters. 13 elements will have fairly-narrow *beamwidth*, but it will give you lots of *forward gain* and excellent *front-to-back
ratio*.

If you need more background info, look up the terms I've underlined above using Google. There's excellent stuff on the first half of the results page. You'll even find good videos on the subject there.

I think Cushcraft made a 13 element two meter beam fifty years ago,
if so it was most likely a SSB beam designed to be used horizontally and
tuned to the bottom of the band. (144 to 144.5 MHz.)
But I am fairly sure it used a GAMA matching system.

A picture of of how the elements are mounted on the boom might help
identify it.

Not to create controversy, but climbing belts shouldn't be considered safe. Sure, they were used for years, but that doesn't make them safe. I'd like to give my slant on personal climbing safety. A tough and scary lesson learned by W1JCW for not having the right lanyard. I'm am glad you are OK John.

Climbing harnesses with climbing double shock lanyards, safe. Climbing belts, regardless of lanyard arrangement, not safe. If one falls with a belt while climbing, the lanyard catching you will bend you in half from inertia and slam your head into the tower leg. If you fall with a harness and the lanyard catches you, it won't feel good, but you stay upright and it doesn't bend you in half and slam your head into the tower. With a belt, if one is knocked out and flips upside down, what is to keep you from falling out of the belt? Answer - nothing, even if it has the leg straps. With a harness, the climbing lanyard attachment point is in the middle of the upper back and if the climber is rendered unconscious while climbing, the climber is still going to be hanging in an upright position. If the climber has the positioning lanyard in place to do work and something renders him unconscious and he does flip inverted somehow, the shoulder straps keep him in the harness.

And free climbing, like I have seen so many of my friends do up a tower without using the dual lanyard system is just foolish. And I've told them so. I like my friends too much to not say something. Do some still do it? Yes, unfortunately.

For this reason, climbing belts were long ago made "unapproved" in commercial climbing applications. One should never cut corners on climbing equipment or buy used climbing gear. Minimum cost of a decent low end (but safe) harness and dual shock lanyards is around $250. It's a small price to put on your life. A really nice one with 6 attachment points, padding and a seat (to stop compartment syndrome) for extended tower work is about $400+. Then the 6' rope positioning lanyard is about another $40. And adjustable one is over $100.

And you should buy the correct shock climbing dual lanyards with the right clip attachments you have on your tower. I like the big open 3" snaphooks with the 3.6M rated gates ,as they will work for just about any tower, but do cost a bit more.

Here is a new one for you; Bought a safety belt at Dayton so I would not have to borrow someone else when I needed to go up the tower. I have the old Standard (a fore runner of Rohn) tower which uses the "X" crossbars instead of the common Rohn which uses the "Z" pattern. About half way up, the snap "snapped" firmly in place. I did not realize that as the tower got higher the crossbars got smaller, and that "snap" I heard, was the sound of the clamp making a very fi! rm grasp of the crossbar because they were almost identical in size and, in which I could not get to release. I saw my neighbor come home from golfing but could not get the courage to shout at him, and I knew my wife could not hear me. The only visions I had was the local fire department with their boom truck in my back yard. After "dangling" up there for about 15 minutes (which ed seemed like an hour), and sweating up a storm, I finally got it to release and decied that was as high as I was going up tonight, and until I find a work around.

Thought this might give someone a chuckle

The Smoke Test is an old Ham Radio test where you hook up a component or piece of equipment, apply power, and see if it smokes. Tune for maximum smoke and minimum burn.

It is an old saying "tune it up and see if it smokes". The Smoke Test is just really a test to check for continuity. The idea is that if you apply power and no smoke, good. If you turn it on and no smoke, good. If you tune it up and no smoke, good. If you transmit and no smoke, good. Smoke at any point of the procedure is bad. I knew an old auto mechanic who when looking for a fault in wiring that was blowing a fuse, would cut a piece of copper tubing the size of the fuse and place it in the fuse holder, then stand back and look for smoke. The smoke usually came from the faulty shorted wire.

In older equipment in older shacks the Smoke Test was a valid way of testing equipment - a little smoke would not kill most equipment; nowadays it only takes a little.

Anyway, the Smoke Test is the initial trials of any piece of equipment, just checking it out to see if it works.

Well put Scott, also not forgetting a proper hard hat. I once saw a colleague come a cropper when not wearing a hat and he made an awful dent in his head! Nothing too serious but he was sporting a big scare for the rest of his life.
If you are not confident then don't do it, get someone else who is fully able and experienced to do it.

Not to create controversy, but climbing belts shouldn't be considered safe. Sure, they were used for years, but that doesn't make them safe. I'd like to give my slant on personal climbing safety. A tough and scary lesson learned by W1JCW for not having the right lanyard. I'm am glad you are OK John.

Climbing harnesses with climbing double shock lanyards, safe. Climbing belts, regardless of lanyard arrangement, not safe. If one falls with a belt while climbing, the lanyard catching you will bend you in half from inertia and slam your head into the tower leg. If you fall with a harness and the lanyard catches you, it won't feel good, but you stay upright and it doesn't bend you in half and slam your head into the tower. With a belt, if one is knocked out and flips upside down, what is to keep you from falling out of the belt? Answer - nothing, even if it has the leg straps. With a harness, the climbing lanyard attachment point is in the middle of the upper back and if the climber is rendered unconscious while climbing, the climber is still going to be hanging in an upright position. If the climber has the positioning lanyard in place to do work and something renders him unconscious and he does flip inverted somehow, the shoulder straps keep him in the harness.

And free climbing, like I have seen so many of my friends do up a tower without using the dual lanyard system is just foolish. And I've told them so. I like my friends too much to not say something. Do some still do it? Yes, unfortunately.

For this reason, climbing belts were long ago made "unapproved" in commercial climbing applications. One should never cut corners on climbing equipment or buy used climbing gear. Minimum cost of a decent low end (but safe) harness and dual shock lanyards is around $250. It's a small price to put on your life. A really nice one with 6 attachment points, padding and a seat (to stop compartment syndrome) for extended tower work is about $400+. Then the 6' rope positioning lanyard is about another $40. And adjustable one is over $100.

And you should buy the correct shock climbing dual lanyards with the right clip attachments you have on your tower. I like the big open 3" snaphooks with the 3.6M rated gates ,as they will work for just about any tower, but do cost a bit more.

Here is the specs for Cushcraft 13 element

beam.
73 Ken

http://www.cushcraftamateur.com/pdffiles/951410.pdf

The Cushcraft 13B2 Boomer is a 2 meter wideband yagi for FM,

Packet, CW and SSB. Mast shown is not included.

13B2 Specifications
Frequency: 144-148 MHz
Elements: 13
Gain: 15.8 dBd
Front To Back Ratio: 26 dB
VSWR 2:1 Bandwidth: >4 MHz
Power: 2000 watts PEP
Longest Element: 40 inches (1.01 m)
Turning Radius: 8.9 feet (2.7 m)
Boom Length: 15 feet (4.57 m)
Wind Surface: 1.8 sq. feet
Connector: UHF (SO-239)
Weight: 6.7 Lbs (3.1 kg)
Specifications are subject to change without notice.

PacketRadio is Still Alive.....Mississippi.....145.010.....Simplex.....1200 baud
Baud

I dont believe it's a cushcraft. Here's a picture and look at the coax matcher I was told it was a beta match.

Just my 2 cents.....

Ran into a problem similar on all bands. Turned out to be a computer power supply - in a desktop.

Changed the power plug to a "CORECOM" one. Cost less than $10 on eBay

Chris, I have been reading
the responses and following this thread since my last
answer. I did not know that the antenna had been remade. I
would also agree with others about reciprocity regarding if
you can transmit, then you should be able to hear them. I
think a problem might be either in your location (which
cannot be changed) or in something producing some form of
electromagnetic radiation, which you cannot obviously hear,
yet it is interfering with your reception. I would start
doing some tracking with a portable battery operated
receiver, just to see what you can see. I have the same
radio, a Kenwood 440S/AT and would not give it up for
anything, and would say you should not give yours up either.
This is a good radio and mine has performed admirably both
in ham service as well as AFMARS service. Just my $0.02
worth.   73 de KCØJPO/AFA8JP

I use another type of smoke test for big HF antennas at my last qth, put them up on a tower or on the roof of the house then stand in the garden and smoke a few cigarettes, if the Mrs or any of the neighbors dont come out threatening to cut off parts of your body or try to make you wear the antenna its ok to start other testing!
Sounds like a nice antenna only got 4 elements on VHF myself and its in the loft after a failed attempt to roof mount due to restrictions at this new qth, it still works ok and there is enough room up there to get full all round coverage in a vertical mounting position for FM simplex and repeaters with a small sat dish rotator mounted in a sturdy garden parasol base and a 1m FG pole.
Good luck with it hope all goes well.

G. i am very interested to know how your 80 286ft loop works out , and at what height you put it up , will you use an ATU ? I have the room to put up such an antenna, been considering it since i got back in this Great hobby a few months back, now using a OCFD, has 4-1 balun and i use an ATU Z Match emtech-2, i only run 5 watts , but this winter will work on a SS Amp .

AJ, I also run a 80M size delta loop, tuned to the center of the 20M phone band. Fed with coax and a 4:1 current balun at the feed point. I use it on all bands 80 thru 6. It does need a AT on 17, 80 and 30 but good points on the other bands.

1X loop is a 100 Ohm antenna , a 2X loop and larger close to 200 Ohm

2X in length loop, or greater can be matched with 50 Ohm coax and a 4:1 Balun if

the overall length of the loop is a multiple of the length at that frequency

Even Multipliers will make it a resonate antenna, A 4X and 8X loop will match

the most bands when used with a 4:1 Balun

With the correct resonate length of the antenna no tuner adjustment is needed

From: Billy McFarland
Topic: 32536 Message: 32561

Just thought I would share this story with you all.

I used to have a Vauxhall zafira motor car this had lovely metal roof bars that a nice 3/8 thread could be attached to. I tried mag mounts and all sorts but the long whip a mfj1979 used to tip over even with the strongest of mag mounts.

I sold the car and got myself a new Dacia Sandero. I attached a mag mount to it. Could not get the swr down from about 5:1 on any band. Clearly had an earth issue. I even got a loan of the huge triple mag mounts and still not a good earth. Finally realising that the car had more plastic than metal in the body I had a brain storm (and if anyone has thought of this before then I do apologise but it's the first for me)

I welded a 4 inch square plate 1/4 inch thick to the towing eye (the towing eyes are an inch thick threaded rod which gets screwed into the car chassis for towing when you brake down) then fitted a 3/8 thread to so239 connector on the plate. Ma crewed the towing eye in and attached the mfj 1979. BOY what a difference I could get a 1.3:1 swr to 1.5.1 swr on all bands... Well I'm over the moon easy to set up as well for mobile use. (of course stationary operation only)

Hello billy

Nice rework of the tuning box

....

Self resonance of your choke is (from manufacturer) 25 megs

Hmmmm it is a vhf choke so maybe a bit low on inductance?!?

If it will resonate on 12m what does it with the antenna ...

Will a strong 12m signal blow the choke ?

Sigi,

Not sure yet.... That's what amateurs do right? Fit parts and see if they blow up :/

This type of RFC was suggested by an EI station who conducted some tests (if I find the website ill link it here) where it seemed to work well.

I'm sure it comes up in google if you type cushcraft r7000 match box.

I have the Jacklite and use it for an HF end-fed and a roll-up J pole. I think it might be too light for your use and would bend if your antenna has any weight.

I play with fiberglass and metal surplus tent poles. They might be of use for you but they would need to be attached to something or guyed. I bought some ceramic rings that have 4 drilled holes and put one at the top. I attach a ring to that and run a line through it so I can raise and lower antennas. Guy wires can be attached as well.

The poles are inexpensive but shipping is the killer. Check them out on Ebay and wait for a hamfest.

14ga will handle anything you throw at it with 800W. The balun will depend on the size of the core you use. Check out a copy of Jerry Sevick, W2FMI book for more different types of baluns and power ratings. I use a duel rod Guanella 4:1 in a weather proof box at the feed point. My photo album also shows a switchable 4:1 or 1:1 rod type balun I use with a ladderline for a 160/80 fan antenna.

32580. RF everywhere

Yahoo group: ham-antennas (2014)
Date: 2014-05-31 01:20:26 UTC
From: Alex Netherton
Topic: 32580 Message: 32580

OK folks. I went and retrofitted my 20 meter dipole into a center fed balanced wire antenna. I have been using a MFJ-1777, a 102 foot center fed for about a year, and in that year, have amassed 65 countries (not all confirmed). That is just in 1 year - I have been licensed since 1979, and probably have a few more countries that I have no record of, but 65 is not bad, as I get bored, and do not operate for more than a couple of hours a day, and a couple or three days a week.

Anyway, the retrofit of my dipole is a dismal failure. I tried to use it today, and there is RF everywhere, especially when using my SB-200. The shack is grounded, both to ground, and to the house ground. I was trying to get Croatia on 20 (9A9A), and was having fits with my rig (FT-950) and RF feedback. I finally got disgusted and went back to the MFJ antenna (which is a similar construction, only longer) and got him first try. With the 20 meter antenna, I actually got a RF burn from my mic! On the longer antenna, no RF, no burns, no problem. Antenna works from 80 thru 10, and if using the LDG AT-100ProII tuner (without amp), it will tune 6!

I am using a Heathkit SA-2040 tuner, and run either the rig barefoot, or with a SB-200 (yeah, I know, but I like old stuff, and it works - if I am careful, even on 12 and 17!).

I am stumped. I have used a similar antenna, cut for 40 meters, in the past, with not too much problems, though I was using tube radios then.

All equipment grounded to a ground bar, grounded to earth and house ground. Help!

Alex

Earth (AC Power and DC) ground is not always synonymous or the the same thing as RF ground. If it was shunt fed towers would never work as verticals

Tell us about your grounding system(Number of ground rods, depth , spacing, general soil type, etc), also when it comes to RF ground the length of the wire from the shack grounding point to the ground rods can be a significant factor .. a 16.5 foot long ground wire (typical 2nd story shack) is essentially a RF open circuit on 20 meters as an example.

Next the feed line length on the new antenna can be such that you have a voltage maximum at the shack, you could try changing the feed line length adding 16.5 feet to the feed line and see if things don't improve on 20M (might get worse on 40M though etc)

Things to ponder

Does your tuner have a balanced output or just coax connector.

Refer to ARRL antenna book 16h edition section7-20 it looks like you need to add a balun at the feed point whether its a coax or balanced feed line ratio 1:4 or higher. Due to you having changed the impedance balance see page 7-21 balun requirement

Have you re-profiled the antenna using a rx noise bridge or antenna analyzer.

I got rf on the mic when I had really bad mismatch between the antenna and a coax feedline when I left out the coax matching section between a loop antenna and coax feedline.

I finally got disgusted and went back to the MFJ antenna (which is a similar construction, only longer) and got him first try. With the 20 meter antenna, I actually got a RF burn from my mic! On the longer antenna, no RF, no burns, no problem. Antenna works from 80 thru 10, and if using the LDG AT-100ProII tuner (without amp), it will tune 6!

I am using a Heathkit SA-2040 tuner, and run either the rig barefoot, or with a SB-200 (yeah, I know, but I like old stuff, and it works - if I am careful, even on 12 and 17!).

I am stumped. I have used a similar antenna, cut for 40 meters, in the past, with not too much problems, though I was using tube radios then.

All equipment grounded to a ground bar, grounded to earth and house ground. Help!

This antenna sounds a bit like a g5rv and the best thing you can do with that is use it as washing line ;)

I assume you have the twin feed straight to the tuner? My friend had a very similar problem. What we did to try and resolve it was fit the 4:1 balun at the base of the twin feed and have 50 ohm coax to the shack. The tuner had an easier time if tuning. As previously did the length of feeder and wire is an important thing as it could be voltage maximum or current maximum at the shack end . Also please consider burying your feed line under ground which also helps (not so much on twin feed tho)

Good luck

Rich;

Thank you (!!!) for the time and effort for your work! I have seen the info just fine. -Now, I will have to spend some time to see if I can more fully understand, but this is my issue, not yours, of course!!

In the not too recent past, I have made many loops; -Then, I began to covet the LARGER loops, as the folks that I chatted with on HF were all in agreement of my long past "opinion" that the antenna is best if it is BIGGER AND BETTER. I have a large open field just to the north of the house, so I put up a 2000-plus foot loop, and while it worked, it was very hard to imagine that it would stay up over a Minnesota winter!

I then was beginning to look at 4NEZ2, an antenna modeling app. I was given a very good introduction, and began to consider the antenna structure itself. I decided on a five-sided 1000-plus foot loop at about 38 feet, all well in the clear. (100 feet from any trees, etc.) The modeling app made this antenna look very good, so I built it!

The results were far from what was expected! I tried many methods of feeding, adding counterpoise elements spacing of these two elements, antenna (radiator) height and so on and so on and so on. (This was an eighteen month quest, and I was just not going to give up!

The same fellow that gave me the personalized instruction on how to run the antenna modeling app came over again. This time he (again!) pointed out that the GAIN that I was fixated on was indeed correct. -However, the gain LOBES were not going where one would NEED the RF to go!!! (In the case of 75 meters, there was a HOLE; The shape of the pattern was like a doughnut, in fact!)

So, the magnificent five-side loop came down, and I made up a four-side 75 meter loop, after careful consideration of the 4NEC2 app, this time!!!!

Bottom line: The 248 foot loop worked so very well that I made up a second one. (Same good results.) By the way: 248 feet is too short, one might think? By the 1005/F, yes it is. But the wire that I am using is PVC-coated #14 THHN. As a result, one must add a 4% velocity factor. -This is how I arrived at 248 feet. In reality, it is still too long for ME, as I operate on 3.9 Mhz, as an example. The 248 foot loops are both resonant at about 3.5 to 3.6 Mhz.

Yes, this is a long and rambling reply to your question of my now being able to view the information that you had presented. It is simply my hope that you might find something in my past time-wasters of mega-loops.

Thank you again, Rich!!!

OK FOLKS:

Here are the rules of the reflector : HAM-ANTENNAS
This file will be sent once a month automatically to remind all users.

1. Name calling (race, religion, politics, gender, etc.), is prohibited.
2. Telling someone they are ignorant (in any way, shape, or form), is prohibited.
3. Denigrating other races or minorities, or expressing POLITICAL VIEWS will earn you moderation or banning.
4. If you do it privately it is a private dispute. When/if it spills over onto the reflector, you will be moderated or banned.
5. Even coming close to these boundaries is to be avoided.
6. Banning/moderation will be used, with NO notification to the transgressor.
7. Civil chatter and Civil wordage is THE rule.
8. IF the Moderators are offended, then penalties will be applied.
9. There are two Moderators, EITHER can ban/moderate you.
10. Moderators ARE the final arbitrator of disputes, we hate bickering!
11. USE Private or Direct Emails to address your concerns to the Moderators, because public postings may likely result in penalties as above. !!!!
12. Use common sense. If you would be hurt or upset if you received what you are about to send, and you are intentionally meaning to do that, DON'T DO IT!

13. We ALL would like to enjoy discussion about HAM-ANTENNAS, nothing more.

32588. ATAS-120 as fixed antenna

From: steve.lenaghan@...
Topic: 32588 Message: 32588

I am going to be in Virginia over the fall and winter and taking my FT897D. I don't have room for anything fancy and wondering if the Yaesu antenna with radial kit will work. I looked at several no radial verticals but they have a lot of parts and I really don't want to build and un-build any of them. The Comet CHA-250 is an pricey option, for which I have not heard great things and when I get home I don't need an HF vertical.

The ATAS will be used for the mobile eventually. Ideas??

Good morning, Rick;

Bill has already suggested the Hustler-Newtronics 5BTV or 6BTV vertical antenna. I wish to supplement his recommendation.

I also play on some of the other channels on 60 Meters besides the 5 that are allocated to Ham Radio use.

The 60 Meter Add On Kit available from DX-Engineering for the 5BTV and 6BTV does make them perform quite nicely on 60 Meters on the back of the motor home RV, but I will admit that it is mounted and used only when it is parked -- the 6BTV is about 28 feet long and the bottom mount is on a trailer hitch drawbar that goes into the 2 inch square tube receiver on the back of the motor home which is about two feet above the ground. Also, my main application with the vertical antenna is longer distance communications. Sometimes I need to talk to San Francisco or San Diego from here in the Pacific Northwest.

For NVIS use there are some different dipole type antennas that go onto a balun attached to another coaxial cable on the back roof area, and that is what I use for shorter range NVIS communications. Usually they will tell me what channels they will be using to talk to me. And there are the auto antenna tuners if something comes up and we need to move anyway. So far I have met the specifications in functional communications quality.

And the motor home with all of its appointments and accommodations has really made an effective independent mobile communications station. I can be on station for several days before I need to be resupplied. The radio equipment can go much longer than I can without being resupplied.

Enjoy, and 73;

Ralph, N7KGA

Steve,

I had an ATAS-120 on my car and was disappointed in the performance. It worked OK on 40, but very poorly on the other bands. If you don't already have it, I suggest you consider a screwdriver vertical instead. I used one in fixed mode with about 20 radials with very good success. Worked 32 states on 160, many countries on all the bands. The one I have (KJ7U - Larry's Antennas) will handle a KW. I now have it on my car, and it works FB with the TS-480HX. It requires running the additional DC power cable, but the improved performance is worth it. I suggest one of the models that will do autotune.

I prefer Comet base antenna 146 and 440 MHz rated at 200 watts $75. I have used a 1/4 wave mag mount on both bands. Tune 2 meters high end and the match on 440 is not bad. Of course you can by a dual band mag mount.

Be careful in trying to use a 2 meter 1/4 wave antenna on 3/4 meters. While it can be trimmed to take power on both bands and give a reasonable SWR, but on 3/4 meters most of your radiation will be at high vertical angles and not toward the horizon where you would like it.

You can check many antenna handbook patterns for a 1/4 wavelength vertical operated at 3 times the fundamental resonant frequency and see the results, it makes a fair cloud burner, but not good on the horizon.

Hello Ray,

While I agree with you on the general issue of 3/4 wave operation, at near horizon on my quick shot on EZNEC it comes out at 9 degrees only ~5 db down. As a side note, most repeaters are not on the horizon anyway? When you are looking at a mag mount antenna, it ain't a pretty pattern anyway! It follows an old KISS rule. Low $$, quick install, works. Now if the mag mount was not the criteria, I would go with a gain dual band $$ antenna.

The BR-6070 Dual
Band Base Station Antenna is the perfect choice for those seeking
omnidirectional, high-gain performance at a low price point. This antenna is 63" tall is pretuned and includes a mounting bracket
(for masts less than 2").

Gain is 4.5 dBd on 144 MHz
Gain is 7.2 dBD on 440 MHz

This is the one I use travel trailer, portable, and base. I swept tested it and the match is <1.2:1 on both bands. No connection to either the manufacture or any dealer, just the facts.

32602. AW: [ham-antennas] 2M/70cm antennas

Yahoo group: ham-antennas (2014)
Date: 2014-06-03 22:55:56 UTC
From: siegfried jackstien
Topic: 32593 Message: 32602

On the car a mag mount antenna that is called "earthless" ... would mean about roughly 1m long with a coil in centre

Endfed halfwave on 2m and 2x 5/8 wave on 70 cm

Works superb even if the cuplibg to the roof is not good (all quarterwave whips needs some capacitve coupling to the roof and not all mag mounts are good on that)

... for station use one of the stacked dualband antennas ... be it comet, diamond or huster or whatever

But ... ALL KANUFACTURERS build their antenna the same way ... with "crimped" connections inside between all the parts ...

And most are wiggling even when brand new

So buy one of them and solder ALL connections (maybe adding a small jumper wire across the joint) ...

I did not find any manufacturer with reliable construction in the connections (and I searched a lot for that)

... only way is .. buy a cheap one an solder ... (or buy an expensive model and see that there is the same trouble inside)

I have a Comet GP-15 (a triband) that is a single piece (no center joint) so no internal connectors to solder (or even to get at).

It works well on 2m & 70cm. It's tuning on 6m is for the upper FM end, which was disappointing to me as I would prefer to tune it down to the SSB end.

Hello to all. Hope everyone is doing well. I will be errecting a 8' roof tower on my 25' peak. My question is will schedule 80 aluminum pipe 1.9"OD hold up my small hy-gain 203 ba 20 meter mono band 3 element yagi. I want to raise it 6 feet from the thrust bearing ...Also the antenna will be near trees to block any winds from the west and south. Any input would be helpful. thanks.

Hi tony, simple answer with a question, what is the tower with a 6 foot extension rated for in SQ FT of antenna load. And what is the SQ FT of the antenna. Given a safety margin of 70 MPH. If the tower is rated for that load you are in. If not, rethink the installation..... Cheers,

Mel, K6KBE

Also that antenna has internal joints ... I do not mean that one screw connection that you can find on the x200 x300 (and its clones) ... I mean ALL the internal connected parts in the antenna

It is made internal from several parts (radiator part, stacking coil , another radioator part ... etc.)

ALL manufacturers build their antennas that way (also your comet tribander is made that way!!!)

You have to pull out all the pats from below ... where the coax connector is

I do not know your comet gp antenna but maybe it is build the same way like all other manufacturers make their antennas ... with a set-screw at the base the coax connector is secured ... loosen that and you can pull all parts out

I looked in a dozen different antenna models and ALL have the same fault

When new all is fine ... but after just a few years the joints are corroded

So ... check also your comet

And while you have it out ... maybe you can tune it a bit lower for 6m

Before you ask the question you need to read your homeowners policy in excruciating detail.

The coverage will likely vary by insurance carrier and geographic location (frequency of lightning hits such as in Florida or on top of a mountain) may also be factor.

I did have a buddy with a 100' tower next to the house. After the 3rd direct lightning hit (blew holes in the bedroom walls) I know his carrier refused to cover him for lightning damage anymore as long as the tower was still standing in his yard, his XYL left him and took the kids as well citing "reckless endangerment"

Do you know the PSI of the aluminum? The ARRL book has an Analysis of Antenna Mast Strength excel model that you can use to determine how much wind speed your mast can handle. I used this model for my antenna install.

Good luck!

Sounds like a country song in the making.

I would definitely check your homeowners policy. And also make sure your wife is cool with you putting it up in the first place. Check environmental conditions at your location and engineer it properly.

32619. Portable end-fed wire antennas

Yahoo group: ham-antennas (2014)
Date: 2014-06-04 20:54:49 UTC
From: wa1rkt@...
Topic: 32619 Message: 32619

I've been experimenting with some end-fed wire antennas strung from the rear of my 23-foot motorhome to a nearby tree. Lengths I've been working with are 17 feet, 34 feet, and 50 feet. The antenna is connected to an IC-706MK2G thru an LDG Z11Pro autotuner.

I'm not really getting the results I expected. For example, one would expect that the 34-foot antenna would probably tune pretty well in the 40-meter band using the autotuner (which is specified to be able to tune anything from 6 to 800 or 1000 ohms) and 50 feet should be close enough to a quarter wave on 75 that the tuner should be able to handle it easily. Doesn't seem to be working out that way... 40 and 75 are difficult to tune with 34 and 50 feet respectively, and yet for example 20 meters, and some MARS and CAP frequencies above that band, tune just fine with the 34-foot antenna which looks like approximately an end-fed half wave (high impedance).

I'm wondering if, instead of acting like a vertical antenna with a poor ground, the antenna is acting more like an off-center-fed dipole with the short end a foot or so off the ground.

What are your thoughts?

So, what are the ground(s)? Is one side of the antenna actually the metal shell of the motor home? Is the m.h. grounded? An ungrounded m.h. can look a lot like one arm of an OCF. On the other hand, if there is no direct connection to the m.h., it is still a big metallic object in the near field of the antenna, and will capacitively couple in all kinds of novel ways, like any metal roof.

>> So, what are the ground(s)? Is one side of the antenna actually the
>> metal shell of the motor home?

Yes, one side of the antenna is the metal frame roof and truck frame of the motorhome. The shield of the coax connects to this junction.

Note that, unlike a normal OCF, there is no balun. Thus, one side of the antenna is connected to DC common (the motorhome frame) which normally one would expect would make it act like a capacitively coupled ground (sort of) rather than the (isolated) short side of an OCF.

>> Is the m.h. grounded?

No. This is by design. This antenna is intended for use with, at different times, my motorhome; a Civil Air Patrol 15-foot cargo van used as a comm van; and a CAP 32-foot travel trailer used as a command post and radio shack; any one of which can be plunked down anywhere... often, out in the puckerbrush miles from any civilization... and the likelihood of there being a useable ground is slim (note that 4-foot ground rods don't cut it around here even if we had time in the normal incident/exercise to drive one into the ground and retrieve it later). Thus, the antenna needs to work in some useable manner even with no solid ground. I don't really care what the radiation pattern looks like... I'm assuming that no matter what we do, most of the radiated signal will go more or less up, for NVIS coverage out to a hundred miles or so. That's our target area.

Rick, try a single quarter wave wire from the motor home shell to some above ground anchor as a counterpoise.

I actually did try that, in the sense of laying a counterpoise wire on the ground and extending it in a direction opposite from the radiating part. Didn't make any noticeable difference. I suspect that with a metal frame nominally 23 feet by 7 feet, a length of wire 16 or 32 feet is unlikely to be noticed.

Note that the command post trailer has an ALE radio that hops frequencies in a range from just below 80 meters to just above 15 meters and about 10 frequencies in between (some of which aren't very close to a ham band). Part of my objective is to try to find an antenna length that the command post's tuner will tune do all of those frequencies.

Rick,

Try a 0.025 wave length as the ground and try pegging the end of the short counterpoise into the ground. This has always worked for me:

Hello Billy,

One time in a really dry location, I could not get a good ground. The nite before we made homemade ice cream and I had all of the salty ice water left over. We had a half dozen rebars driven into the ground as far as they would go and still had a poor match to ground. The light bulb went off and I poured equal amounts of the salty water around each ground point. Took about 3 hours before we saw a significant improvement in the match. Like being at the beach..... Success.

32626. Delta Loop Modeling Help

Yahoo group: ham-antennas (2014)
Date: 2014-06-04 22:41:25 UTC
From: Geoff NW7GM
Topic: 32626 Message: 32626

I'm wondering if someone could help me out with a little antenna modeling - I would do it myself but my main system is not set up right now (post-remodel).

I'd like to model a horizontal delta loop. I figured the total wire length to be around 220' - so in the 80m range. Average height will be 20-25' over average to moderate ground (we have lots of granite under us here in the PNW). I'm planning on having my SGC-239 tuner at the feed point so I won't have any transmission line at the antenna except for the RG8, RG8x or 1/4" heliax I have feeding the SGC tuner. I think total length of coax will be about 40' (I haven't had a chance to measure that out yet). I would like it to work 80-10m (maybe even 6m?). I think that should be enough info to get started with.

Thanks,

Geoff, NW7GM
Seattle, WA
CN87tr

I suppose Scotland is always raining and wet and plenty of grass everywhere for a nice ground. We would struggle to get the salt here ;)

What about using one of those Hy end fed antennas? That uses the coax as a counterpoise so you will need an rf choke on the feed surely that would work better?

You might consider a balun of some sort, I suggest a current balun. Maybe 1:4,
maybe something else... pending results.

A choke balun on the feed coax would probably not hurt.

[This response due to Dave AB3NR: Please keep this attribution intact.]

OK, so the m.h. or other metal vehicle is ungrounded, and is therefore
a big, fat antenna element, much like using a 55-gal drum as an antenna
in the VHF. [This is not insane, BTW. There are .mil antennas something
like 55 gal drums.] One result of such big fat elements is a very broad
bandwidth. Another is a bit of loss. You win some, you lose some, IOW.
The broad bandwidth is the same as saying "flat looking curve of SWR

and/or impedance vs wavelength", and this will result in difficulty (i.e. "indecision") in tuning.

I'm going to take a stab at modelling your situation with NEC-2 now, and this might take a while, and might not work. But it ought to show something.

Right now your antenna has three elements radiating: the thin wire, the m.h. body, and the outer shield of the coax feed. The latter might be troublesome because it might really goof up the other two, and indeed being "hard to tune". But because the shack is inside the m.h. this may actually not be an issue. Well, if I learn anything I'll post back here.

Note to other posters in this thread: You might hate me because I can't top post, and I understand. But leave my name/call sign and "headers" showing the attribution of material you quote. This is common courtesy and good practice. Credit where credit is due, blame where blame is due, and the possibility of later emailing an author with questions or comments is possible.

From: Raymond Tompkins
Topic: 32632 Message: 32632

Good Afternoon Group,
I just moved into an area and I have virtually no space for a horizontal antenna and virtually no room for ground radials and a vertical antenna. To make matters worse, the antenna must be unobtrusive. I've heard about flagpole antennas and some mobile antennas that might work. Almost enough to make me a living silent key, hi hi.
I had a Spi-Ro 10-80 meter135 foot trap antenna at the previous QTH and I really, really, liked it. I realize the "new" antenna may not work across the full spectrum of all bands but if something from 10-40 would really be nice. I need just four States on 10 meters SSB to complete 5BWAS.
Any and all help very much appreciated as I have been diligently working the ARRL W1AW QSO Party and would like to get back into the action.

Tony,

Pipe isn't rated to do anything except support itself and carry liquid/gas/wire inside itself.
OTOH, "structural tube" IS rated to withstand bending moment. Tube is specified in OD and wall thickness, as well as material type, alloy, temper, and maximum stress.

There are free calculators available to give you the information you seek. A Google search of mast + calculator provided a link to WD9P's online calculator:
http://www.math.niu.edu/KARC/mast/

I found more interesting links on the subject here:
http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=17127

The mast out the top of my US Tower TX-472 is 15 feet long with 11 feet protruding out the top. The mast is 2" OD x 0.25" wall steel (provided by US Tower). Attached to the mast just above the top of the tower is my Force12 C-4XL 40/20/15/10m yagi (30 ft boom) and at the top of the mast is my Cushcraft AR-10 vertical. Several storms later, and it's still upright.

vy 73,
Bryan WA7PRC

Subjecy: new antenna installation question
    Posted by: Tony K2VI
    Date: Tue Jun 3, 2014 5:03 pm ((PDT))

Hello to all. Hope everyone is doing well. I will be erecting a 8' roof tower on my 25' peak.
My question is will schedule 80 aluminum pipe 1.9"OD hold up my small hy-gain 203 ba 20 meter mono band 3 element yagi. I want to raise it 6 feet from the thrust bearing.
Also the antenna will be near trees to block any winds from the west and south.
Any input would be helpful. thanks.

Tony K2VI

If made a bit higher and not fed in centre but at one side (a quarterwave from top) you would have a nice 80 dx antenna :-)

Buy a flagpole (6-7m) ... isolated from ground

Add an autotuner at the base and hide some radials below it (laid out in the grass and stapled down they will be invisible in a very short time)

Should work 10-40

Raymond,

Can you define "virtually"? Two square feet? One hundred square feet? If you have even a 10' X 10' area, you could use a screwdriver vertical like the Hi Q or Scorpion, and put down a fairly dense set of short radials. (The advantage of not having enough room for long radials is that it is easy to put in lots of short ones.) You could disguise the antenna as a flagpole, patio umbrella, basketball backstop, or, if you want to be creative, a tree. A piece of plastic pipe long enough to hide the antenna, painted to look like a tree trunk, with plastic branches glued on might be just the thing. I used a screwdriver vertical as a base antenna with some success, but I had twenty five tuned radials on the ground.

Other options: load up on the rain gutters, run a very thin (therefore, QRP) wire (invisible from the street) to a cooperative neighbor's house, elevated screwdriver vertical in the attic poking out of a hole in the roof disguised with a vent pipe. I had good success with the latter, using only four radials. (You need fewer radials if the antenna is elevated.)

Where there's a will, there's an antenna.

Good Afternoon Group,
I just moved into an area and I have virtually no space for a horizontal antenna and virtually no room for ground radials and a vertical antenna. To make matters worse, the antenna must be unobtrusive. I've heard about flagpole antennas and some mobile antennas that might work. Almost enough to make me a living silent key, hi hi.
I had a Spi-Ro 10-80 meter135 foot trap antenna at the previous QTH and I really, really, liked it. I realize the "new" antenna may not work across the full spectrum of all bands but if something from 10-40 would really be nice. I need just four States on 10 meters SSB to complete 5BWAS.
Any and all help very much appreciated as I have been diligently working the ARRL W1AW QSO Party and would like to get back into the action.

From: jerrybosak@...
Topic: 32593 Message: 32648

I think you need an Elmer, but at least you were smart enough to come here and ask for advice...

The answer is that you need an antenna for your home and you need a separate antenna for your vehicle..

Home base station antenna's comes in all flavors, some will like this while others will like something else...
My preference is the Diamond V2000 - just due to the fact that it does 2 meters and 70 CM and also 6 meters and is not obtrusive - it's probably 9 feet long...

A even better choice is to use the Diamond X510 - it is almost 18' long.
Even with the ground plane kit, I prefer to put a dozen or more radials out in the yard underneath the antenna....

You also need to have considerations as to which coax to use to feed the antenna. If you are going to work both 70 CM and 2 meters - you will want to use LMR 400 for any run of more then 50'. Belden 9913F7 seems to be the industry standard today for minimum requirements for these antenna's...

On your vehicle you are going to want to buy the best antenna you can get - since the roof of the vehicle is not very high up off the ground and you don't want to leave a lot on your plate - especially if you plan on talking more then a couple of miles while mobile...

The antenna that I use is the Larsen NMO 2/70 - it is getting hard to find.

I also like the Comet / Madol line of dual band 1/2 or 5/8ths wave antenna's..

Always invest your money in the coax and a good antenna...

AB3NR>> "the m.h. or other metal vehicle is ungrounded, and is therefore a big, fat antenna element... a very broad bandwidth. Another is a bit of loss.... flat looking curve of SWR and/or impedance vs wavelength... this will result in difficulty... in tuning."

Why would a flat SWR curve cause difficulty or indecision in tuning?

All the tuner knows is that it sees an impedance of X+/-jY and it needs to transform that into something close to 50+j0. It doesn't know, and shouldn't care, where that X+/-jY comes from or whether the SWR curve at that frequency is wide or narrow.

I'd be happy with a wide SWR curve and the "bit of loss" would not bother me at all... this antenna is intended to replace a 9-foot CB whip with an autotuner at the base (used with our CAP comm van) which may as well be a dummy load at the frequencies just above 4 MHz where we will be doing much of our operating.

I just borrowed an MFJ-269 antenna analyzer with a thoroughly corroded battery box, so as soon as I can replace the battery box I'll be able to do some better analysis.

http://www.balundesigns.com/Wire%20Lengths%20for%209-1%20ununs.pdf"

Wow. A 9:1 unun? Certainly didn't expect that. There are frequencies in the desired range where the impedance is pretty high and I've been considering inserting an MFJ switchable 4:1/1:1 balun, but I would think that a 9:1 unun would result in some unusably low impedances at some points in the freq range.

I guess when I get the new battery box to replace the terminally corroded one in a borrowed MFJ-269, I'll know better what impedances I'm really dealing with.

>
> Why would a flat SWR curve cause difficulty or indecision in tuning?

My thinking is that the tuner is looking for a local minimum in SWR, if the curve is flat it won't find it as quickly, possibly. I.e. it's easier to find the low point in the Grand Canyon than in Kansas, so to speak. I am dubious about this, but it's a talking point. :-)
It depends on the method used to autotune. There is more than one way to skin that cat.

> All the tuner knows is that it sees an impedance of X+/-jY and it needs to transform that into something close to 50+j0. It doesn't know, and shouldn't care, where that X+/-jY comes from or whether the SWR curve at that frequency is wide or narrow.

It depends how the tuner works. Some automatic ones can be heard "hunting", trying combinations of L and C, as if they were carrying out an optimization algorithm; this is why they're "slow" the first time on a frequency, but afterwards have better starting points. It's true that if they could measure impedance and could actually set the L and C accurately, that would be direct, one-step tuning, and some might actually work that way.

Another source of difficulty is when an optimizer finds an unacceptable local minimum, say if it finds a minimum at an SWR of 4. Then it has to discard that point and rehunt. If the algorithm fails (and they can), or is weakly designed, (alas possible -- "Optimization is hard!" said Engineer Barbie), it might find this same point again (and again...).

> I'd be happy with a wide SWR curve and the "bit of loss" would not bother me at all... this antenna is intended to replace a 9-foot CB whip with an autotuner at the base (used with our CAP comm van) which may as well be a dummy load at the frequencies just above 4 MHz where we will be doing much of our operating.

Yeah, I agree this would be an acceptable, usable solution.

I simulated the trailers/m.h with half of a caged dipole of 2.4 m (7.78 ft) diameter about a foot above ground. (i.e. sort of wire model of an Airstream trailer, a "copper sausage", the cage had 8 or 16 wires, but no cross-connection between them -- I was lazy.). The length of the m.h. varied. The single wire was that -- a single wire either coming directly from the center of one end of the sausage, then proceeding at a slant to a height of around 25 feet, or coming from a short vertical section to the top of the m.h., before bending to the slant to the

tree. Feedpoint was right at the wire-sausage connection. This, I admit, is hardly the definitive model, but I suspect it is close enough for "government work".

There was a lot of loss, getting the gain above 0. was a challenge. On 75m and lower gain was around -5 to -10 dBi, possibly acceptable, if 100W or more power is available.

The curious thing was the effect the m.h. had on pattern. At the longer wavelengths, it was obviously directional, with a take-off angle around 45 degrees, and the azimuthal pattern looked like a cardioid, strongest in the direction the m.h. was facing. In the other direction there was an almost null. It is something like the pattern of a more orthodox sloper.

On 40m, the pattern was much more NVIS-ish, no null, more gain. (about -1 dBi).

On 20m, the pattern was a narrow vertical spike. Since 20m doesn't work well on NVIS, I'd call the antenna unusable on 20m.

>
> I just borrowed an MFJ-269 antenna analyzer with a thoroughly corroded battery box, so as soon as I can replace the battery box I'll be able to do some better analysis.

Yeah, if you can construct some graphs of SWR, R and X, vs frequency, from about 2MHz to 20Mhz, I think you'll see about what I did in the NEC2 model. The 269 can also be fed from a wall wart. 12V, I believe. (12 not 13.8, I mean.)

I fiddled the length of the wire some to get resonance somewhere in the 40m band. 7.2 or so, I think.

A couple of bottom lines -- the tune and resonance point will vary with the size of the m.h., and the m.h. does two things: it radiates as expected, and it also couples very well with ground. (I used a "mediocre ground" that is the default in the little program I use. Pennsylvania rocky forest dirt. Dielectric constant = 13, conductivity = 0.006 S/m). I think (guess) I was seeing about -15 dBi losses to ground coupling.

The SWR and impedance curves looked tractable, especially on 40m, and nicely broad-banded. It wouldn't be hard to tune near its resonant frequency.

One thing occured to me: if you're running any power, that m.h. is going to present possible RF burn hazards, particularly if it has any "spikey" places, where the voltage will tend to peak.

Suggestion: Do the plots with the MH-269. Autotuners can sometimes be weak when trying to match the case of low R and high X, which the model said obtains at frequencies less than resonance. (R ~= 8 ohms, X ~= -1000 ohms on 75m). An LC manual tuner might be useful particularly if it is made or modded to allow the operator to switch the positions of the L and the C (i.e. which one is series, and which one is shunted) and to switch whether the shunted reactance is closer to antenna or transmitter. Running the 269 through such a tuner would be instructive, I think.

Another: the suggestions made by others of taking the m.h. out of the system except as a passive element and instead using some sort of counterpoise wire laid on the ground may be promising. I have'nt modeled this. It would possibly be better to get away from the m.h. a wavelength or two, running coax out to a wire/counterpoise pair. No experience with this, though. Just guessing.

If you or anyone is interested in this model, I can supply a "traditional NEC2 Input card deck". It has many segments, and the freebie/ARRL EZNEC won't handle it. Contact me offlist, please.

Software: xnec2c NEC2++ running on Linux.

32656. Best near-real-time propagation prediction/reporting services

Yahoo group: ham-antennas (2014)
Date: 2014-06-05 17:44:22 UTC
From: wa1rkt@...
Topic: 32656 Message: 32656

Are there any services on the net that report or predict the propagation conditions for "right now" or at least for "today"?

Pretty much all I can find are VOACAP-based services like www.voacap.com/prediction.html http://www.voacap.com/prediction.html and I've used a couple of them, and while they're a lot better than nothing they all seem to report an estimate and prediction for an entire month, which doesn't help a lot to determine the best frequency to use for current propagation conditions.

Thanks...

Rick WA1RKT

I use this mostly for 6M but it can show all the bands. Shows DX cluster spots in a map form. You might like it.

From: wa1rkt@...
Topic: 32619 Message: 32658

AB3NR>> "My thinking is that the tuner is looking for a local minimum in SWR, if the curve is flat it won't find it as quickly"

That's not how autotuners work, at least none that I've ever used. They don't frequency-hop trying to find a minimum SWR... they work on the frequency that is fed to them, and try to match whatever SWR they find on the antenna side to 50+j0 ohms as closely as they can. They couldn't care less how flat the SWR curve is... if you move frequencies and the complex impedance on the antenna end changes a lot, a little, or not at all, the tuner will still tune that complex impedance to 50+j0 ohms if it can. Sometimes it can't come close in which case it will give up after a while and report failure by blinking a bunch of LEDs on its front panel, or by some other means.

AB3NR>> "Some automatic ones can be heard 'hunting', trying combinations of L and C, as if they were carrying out an optimization algorithm; this is why they're 'slow the first time on a frequency, but afterwards have better starting points."

The better ones, or probably pretty much all of them by now, store matching settings in memory for each frequency tried, up to their memory capacity. You dial in a frequency and if that frequency (+/- some tolerance) has been successfully tried before, the tuner starts with the stored settings and if the match is close enough (usually <1.5:1 or <1.7:1), the tuner stops there. Otherwise it searches for a better match in the way that you describe.

AB3NR>> "if you can construct some graphs of SWR, R and X, vs frequency, from about 2MHz to 20Mhz, I think you'll see about what I did in the NEC2 model. The 269 can also be fed from a wall wart. 12V, I believe. (12 not 13.8, I mean.)"

The MFJ-269 is happy at anywhere from nominally +11 to +18 volts.

I didn't want to mess with wall warts, though. There are times when I'll be using this with no AC available. The battery box was $1.95+$4 s/h from MFJ so I just went with that.

Point taken about the possible RF burn hazard. We're running 100 watts, like most people who run mobile, and so far I haven't heard of anyone getting a burn from touching the body of a car with a mobile rig feeding a hamstick or screwdriver, but I can see how it would be possible. My guess (you're pushing the limits of what I know about this stuff) is that there is enough capacitive coupling to the ground to bleed off most of the RF voltage... which, again, points to this antenna acting more like a vertical with a poor ground than an OCF dipole.

Point also taken about taking the motorhome out of the picture and running a separate counterpoise. I could try that although it can't be done with the travel trailer without a lot of work (reason is beyond the scope of this discussion). I also have a different field antenna that is a dipole (can be configured as center fed or OCF) fed with window line and a balun, that I can use if there are enough support points. It could be used as an inverted V but the ends really do have to be high enough that no one can touch them... there is a very real and dangerous hazard of RF burns there especially if the antenna is near a half wavelength or odd multiple.

I have participated in ARES exercises from the local high school which has this big and beautiful flagpole in front, which isn't used on weekends... hoist the center of the inverted V up that flagpole and tie off the ends, and it works fantastic.

Just as additional information

I have suffered thru HOA and Restrictive Covenants and used Attic antennas with decent results. A whole Big subject in itself.)

But that is not my reason for writing.

Be careful with a Flag Pole antenna. Only because some HOAs do not allow Real Flag Poles (antenna or not). They RESTRICT you to simple little short poles attached to the side of house or such.

So check your paperwork or ask .

Best of luck!

Hi...

Have you tried WSPR? I'm not a DX chaser, but it looks like a pretty neat page; you can select the time periods, bands, and frequencies. Just take a while to learn to manipulate the page so the information is useful to you.

Propagation Map | WSPRnet http://wsprnet.org/drupal/wsprnet/map

What is WSPR... find more info here.....

WSPR - Distant Whispers http://www.g4ilo.com/wspr.html

http://www.g4ilo.com/wspr.html

WSPR - Distant Whispers http://www.g4ilo.com/wspr.html An article describing WSPR, an application for receiving and transmitting low power beacon signals on the amateur radio short wave bands.

How about a tent pole, the type that you have to feed through the tent. It would also pack up quite small for storage. Get the longest one you can, tape some wire to it and a 9:1 un un earthed to the body and a tuner. It would need guying when using it as a vertical. I have a pole and the 9:1 un un but have just sold my van so not had the chance to try it out.

When I go camping the mountains with my Elecraft KX3, I use a homebrew end-fed vertical, based on the plans at the EARS web site in Hawaii:

http://www.earchi.org/92011endfedfiles/Endfed6_40.pdf

The unun is simple to build, and this antenna works very well with my KX3 on 40-10.

My vertical support for it is a 28 foot long JacKite, web site is:

http://www.jackite.com/product_info.php?cPath=41_44&products_id=131

I use some velcro strapping to hold the bottom section against a fence post, car bumper, or whatever is handy. The end of the end-fed vertical is connected to the top of the fiberglass pole and the pole is extended. Works great, and stores down nicely into a four foot assembly. Feed line is RG-8X coax to the unun.

Worth considering.....

Sometimes it can't come close in which case it will give up after a while and report failure by blinking a bunch of LEDs on its front panel, or by some other means.

I didn't mean that they varied f, f is fixed. What they vary is L and C. Then SWR is taken to be a cost function. The problem can be stated as "given f, find L and C such that SWR is a minimum." Sometimes there are two C's. Notice that this is problem has two variables and one answer, hence there is no unique solution.

I've never heard of an amateur grade autotuner that could measure impedance. Measuring SWR is easy. Measuring impedance is hard, especially at RF. (The Z values from the $300 MFJ bottom-barrel amateur grade meters can't even sense the sign of reactance. Amateur equipment, I believe, *calculates* Z from SWR using formulae that involve a square root or a square -- loosing sign information. I don't think you can do non-linear optimization of a function very reliably if there's sign ambiguity.

I perhaps misled with "flat". I was guesssing that flatness of SWR vs f implied flatness of SWR vs L and C.

Yes. The long hunt is when the stored value fails.

We're running 100 watts, like most people who run mobile, and so far I haven't heard of anyone getting a burn from touching the body of a car with a mobile rig feeding a hamstick or screwdriver, but I can see how it would be possible. My guess (you're pushing the limits of what I know about this stuff) is that there is enough capacitive coupling to the ground to bleed off most of the RF voltage... which, again, points to this antenna acting more like a vertical with a poor ground than an OCF dipole.

Most people don't key down a mobile when they see someone grabbing the bare metal car/truck body. Radials are buried or elevated above reach, insulated and tagged with hazard streamers. Operators inside the m.h. are probably immune, but RF is tricky stuff. (Fizzix class: "All charge and current is on the surface of a conductor.")

"Enough coupling to bleed off the RF", I think you are just hoping this is true. You're thinking of the RF as building up a static (DC) charge which then is a hazard. Static charges do not come from variable voltages. It is the instantaneous RF charge (voltage) that is the hazard, and that is renewed "frequently". The wind can generate the DC charge, (why parked aircraft, gasoline trucks and other things are grounded), but that's not the issue, I think.

To test this, I use a caged dipole whose lowest point is 1 foot above ground. (I.e. two 15 foot motor homes, one as each arm. Call it the "Airstream Special". Or "Errorstream Folly".) This antenna is resonant at about 11 MHz, at which point it has a gain of -3 dbi. This is similar to a wire dipole at 1.5m above ground. Is a 14 ga dipole at 1.5m safe to grab? (The Special is a viable antenna. Lousy, but it would work. This means there are reasonable currents, therefore reasonable voltages on it.)

Let me put it another way: construct a sheet of aluminum, fifteen feet in length and maybe ten feet wide. Put up a sign, "Baby Zapper", with a picture of a grinning clown and a kid bouncing on it like a trampoline, with lightning bolts surrounding it. Suspend the Al plane a foot above ground on rubber insulators. Connect 100W of RF to one edge of it, connect the other arm to a wire antenna. Your neighbor's three-year-old semi-moron child, its shoes and hands wet with a saline solution (sweat or "another bodily fluid", say), reaches out to the sheet of aluminum. "Bouncy Clown!" it gurgles. A personal injury lawyer is hiding in a blind, videotaping. A thought-balloon above his head features a new Porsche and a flashy girlfriend.

I confess the analysis is faulty, but it's not bizarrely wrong. I've
been only very sketchy with it. I can dump out the gory details of a
NEC run and get you the currents and voltages, if you want. I wish I
had a better model of the m.h., and I could make one if you want.

Caveat: I haven't gone the full route with NEC, tweaking segment sizes
and intersection angles and so on, I was just after qualitative results.

> I have participated in ARES exercises from the local high school which has this big and
beautiful flagpole in front, which isn't used on weekends... hoist the center of the
inverted V up that flagpole and tie off the ends, and it works fantastic.

I bet it does! I made a few runs with a conventional 40 m NVIS dipole
(at about 4 meters above ground) and the large trailer (30ft) nearby,
at varying distances from 10 m to having the dipole directly above the
vehicle, separation only about a meter. The vehicle was not connected
to RF nor was it grounded, just sitting there on tires. The NVIS dipole
functioned well. I was thinking there might be some director/reflector
action from the vehicle, but if there was, it was insignificant. Or I
didn't notice any.

Good luck with your project! (This has been good fun, BTW.)

I am not sure but I think you have lost all your work as you must start from scratch at the new location . Good luck Chuck Wq5B

On 6/4/2014 6:22 PM, Raymond Tompkins kq6x68@... [ham-antennas] wrote:

Good Afternoon Group,

I just moved into an area and I have virtually no space for a horizontal antenna and virtually no room for ground radials and a vertical antenna. To make matters worse, the antenna must be unobtrusive. I've heard about flagpole antennas and some mobile antennas that might work. Almost enough to make me a living silent key, hi hi.

I had a Spi-Ro 10-80 meter135 foot trap antenna at the previous QTH and I really, really, liked it. I realize the "new" antenna may not work across the full spectrum of all bands but if something from 10-40 would really be nice. I need just four States on 10 meters SSB to complete 5BWAS.

Any and all help very much appreciated as I have been diligently working the ARRL W1AW QSO Party and would like to get back into the action.

A very low cost but great performer would be the trap inverted L.
Use the dimensions for the W3DZZ and get the vertical section as high as possible.
If you get the vertical up to 30 foot the horizontal leg would only be 24 foot.
I've made one and mine is now up at 40 foot on the vertical. I have also added a 80 metre trap so that it covers all bands.
It is a great performer on ALL bands, even 6 metres.
It performs at least as well as my Butternut HF9V and cost a great deal less.

An excellent recommendation if this antenna will fit into your garden.

Subject: RE: [ham-antennas] Vertical Antenna in Limited Area

A very low cost but great performer would be the trap inverted L.

Use the dimensions for the W3DZZ and get the vertical section as high as possible.

If you get the vertical up to 30 foot the horizontal leg would only be 24 foot.

I've made one and mine is now up at 40 foot on the vertical. I have also added a 80 metre trap so that it covers all bands.

It is a great performer on ALL bands, even 6 metres.

It performs at least as well as my Butternut HF9V and cost a great deal less.

What you need is a DI box transformer. They are small. A Proco DBT-1 or a Jensen JT-TB-E will work. (There are others of course) Sounds like you need the Jensen for that high impedance, which is more money of course.

But honestly, it's not worth the hassle and $$ and your drive will be quite low. The results will be better to replace the mic with a Low-Z mic. If you like the mic body you have, simply replace the element.

Yes, Mouser sell a replacement cartridge hi impedance, or the electro mikes work very well. You will have to add a battery or take the voltage from the transmitter mike connector for the cartidge. I have two that I modified that use electro mike cartridges, one from an old computer and one from RAT Shack.

!!! That's a great question! In other words, does Raymond need DX or short range? Maybe a subtle directional antenna, say a wire Yagi or little array of verticals on 10m? A closed-spaced wire Yagi on 10m is only about about 15 ft (5m) wide, can be fairly low to the ground, can be made out of wire or even 4 telescoping whips.

Monobanders are so much easier to specify and to hide. A 10m 1/4 wave vertical, with elevated radials is eightish feet high (8+elevation), and eightish in radius of its footprint. But elevated radials can be shortened by loading them! While 10' is normal for elevation, 2' works, too. One insulates the radials and perhaps slacks them when not in use.

Anyhow, you took the question right out of my mouth!

32677. Carolina Windom configuration

Yahoo group: ham-antennas (2014)
Date: 2014-06-07 14:19:04 UTC
From: W1RAM@...
Topic: 32677 Message: 32677

I have an Off Center Fed Carolina Windom for 160-10M that is approx. 260 feet long and which I am trying to fit on to my property. Because of the considerable effort required to get this antenna up over a number of trees, I need to find out ahead of time the pros and cons of several configurations, all of which will require my bending or drooping the wires in a certain direction. Here are two layouts and I'd like to know what will happen to the radiation pattern in each, especially on the higher bands.

1) Keep the antenna wires essentially horizontal and have the final 30-40 feet of the long leg (175 ft.) do a dogleg at about a 45º angle.

2) Keep the antenna wires essentially horizontal except that the final 30-40 feet of the long wire will slope downward so that the end insulator is about 8 feet off the ground.

The feed point will be about 50 feet above ground and the wires will average around 35 feet above ground. Will the radiation patterns on 160-10M be noticeably different in #1 or #2 as compared to a normal OCF antenna that runs in a straight line? I hope someone out there can help me out. Thanks!

Ray,

I assume you're at the P.P. address given on QRZ. I see your problems and they are made of rocks. Nevada should be easy enough, at least the Reno area. Oregon and Montana, well, that's some pretty rough country between you and them. I'm thinking you're in a valley and the issue will be getting a takeoff angle low enough to reflect from F2, but high enough to clear the mountains. Delaware, well that's going to be hard. (Easy for me (Pennsylvania), hah hah!) Compounding things are the relatively low ham population of DE and MT. My rough guess says it might be easier to work Australia or S. Asia than Montana or Delaware. All that saltwater!

So I'd suggest that the first accessory you need is a Jeep or equivalent. If there is a road up to one of the ridges that seem to run E-W to the north or south of your QTH? If so, then I'd take a tripod+mast up there, and some kind of light weight antenna, preferably one with some gain. (A vertical, like a vertical dipole [no radials] might be your best shot at Delaware. There's a lake S of you, maybe the west coast of that lake might be a good launch site for a vertical to Delaware.) I know it's not PA out there; here sometimes a road runs along the top of ridges; in the Rockies, not so much! But just getting to the S side of your valley, and anywhere up the face of that ridge (if I can read the map) would give you a fair shot at OR and MT, and fish-in-a-barrel at Reno. Going up the S side of the ridge N of you gives you Las Vegas. It might be fun to scout out locations with just a receiver and a whip.

For Oregon and Montana, it might be fun to make and deploy a Moxon directional beam. This is basically a 2-element Yagi, with the ends of the two elements bent in towards each other, almost meeting. There's a program by W4RNL, Cebik (SK) out on the net, easily found, to design them. (Or ask me, and I'll run it. I translated it to C for *n*x.)

Also an option would be a Hentenna, a design out of Japan, which has +/- the characteristics of a dipole, but is vertically oriented (hence easily suspended from a portable mast). There are websites about these, too.

Both Moxon and Hentenna can be cobbled out of wire and some PVC (etc) spacers. The Moxon on 10m has a footprint of 12 ft x 5 ft, +/-, ~11 dbi gain. I'm pitching the Moxon because it's about as good as a regular two

element Yagi on gain, doesn't need an exotic balun or matching network, and is fairly compact and can be light weight.

If you can "portatate" a 25 ft mast to a better site, I think you'd be in business. Even 15 ft would serve for a Moxon.

A third possibility is a portable quad loop. Two 2.5 meter PVC spacers, a mast, maybe a 2:1 balun and you're on the air.

All this assumes the alternate locations are within your certificate's allowed radius. My suggestions are for temporary setups to get the award, then worry about permanent antenna(s) at your base station.

KQ6X:

It looks like you may be out of luck with the 135-foot trap antenna, but tells us more about the location. Type of building (single family, multi-family, one story, two or more stories, material (wood, masonry, metal siding or non-metal siding), whether you have an attic and access to it, etc. There are a lot of tricks that can be used to have a working station, but we will just be guessing without knowing the situation.

Raymond,

By now I "assume" that you've looked into the WAS/5BWAS rules and found the there is a 50 mile limit on where you work your stations from. I got shafted by that rule when I retired. Had been living in Martinez (SF East Bay) for 17+ years and was close to 5BWAS. I retired in 2007 and in 2010 we moved to Folsom. That's about 85 miles. Ouch. Started all over on 5BWAS.

We live in an area where no ham antennas are allowed. Hahaha… No one can see them, as I've got 'em strung through the redwoods and liquid amber trees. I have a 45-foot high, 88-foot long doublet (450 ohm feeder) for 40-6 meters, Inverted L's for 80 and 160 meters, and just last month built and installed a ¼ wave 30 meter ground mounted vertical. The vertical is made out of aluminum tubing and I spray painted it with green and black camo paint from Ace. With this antenna setup I was able to complete my 5BWAS back in March of this year. The New England states were tough on 80. The close-in states were tough on 15 and 10, as you are finding out.

What helped me a LOT was participating in the ARRL Sweepstakes contest (looking for states, not to win an award!), the North America QSO Parties, and the K3UK QSO Sked web page. That last one really made it happen as far as finding guys in Utah, Idaho, Nevada, and Oregon.

Hope that helps - 73, Jim / W6JHB

It is only 23 hours, but the ARRL "field day*" is an opportunity to
locate station's *location* without calling CQ and there are probably
more stations on the air at one time than any other day of the year.
And most stations have competent operators.
* the first full weekend in June every year.

You didn't completely explain which way things are going, but if the
MIC is 250 Ohms, put the transformer in the transceiver.

It should have worked, if the mic works and the radio works and you wired it up right. I think it was a hi-Z mic, going into a low-Z input on the radio, right? Make sure you have it wired that way.

"Balanced over non balanced audio."

There are probably no balanced audio lines here, so I don't understand that comment.

"Mic is 3 wire radio is 4 wire."

The number of wires is most likely irrelevant. Both the mic and the radio probably use only 2 wires for the mic element. The other wires may be for PTT, and either unused or something else. You need to know which wires you are hooking it up to. It's not a matter of "try these and hope it works".

Regards,
Andy

If its horizontal with all attachment points 20-25', raising it won't help 80 much unless you raise it really high.

It will be a cloud burner on 80, a little better on 40.

The third and fourth harmonic will look the best so 20 will be a cloverleaf pattern. Elevation angle about 35°.

This based on my printed plots of my 323' loop at 20'. I have plots for 50' as well.

15m pretty decent pattern, el 25°. At 15m and really even at 20m its starting to have pretty significant nulls and peaks. Higher in frequency, the lower the elevation take off angle and the more peaks and valleys (nulls).

It's a pretty good all band antenna.
I use a manual tuner. 6-80.

I won't be getting rid of it but my quiet vertical has a better s/n ratio on some bands 10&20 come to mind.

My thoughts are:

Hy gain patriot series like AV-640

Antron 99

End fed 31' wire with 9:1 Balun with counterpoise or like the EARC sell with the coax as counterpoise for 6-40.

Some use the end fed and counterpoise with a SGC remote tuner.

I have one of the EARC 6-40 units but have not tested it fully. 3:1 swr or less on 6-40 100w. I think $50 delivered us mail 50 states. A little more noisy than my big Hy gain HyTower vertical.
Impressive for something you can put up in 30min or less.

Keep brainstorming, where there's a will, there's a way.

I've heard a couple stations using screwdrivers in the flower bed with radials.

32691. RE: [ham-antennas] Vertical Antenna in Limited Area

Yahoo group: ham-antennas (2014)
Date: 2014-06-09 20:42:42 UTC
From: jim burns
Topic: 32632 Message: 32691

Using a slingshot and a ½ ounce fishing sinker I have managed to get a 6 lb. test mono line into a very good tree limb in my back yard at about 50 feet. I used the 6 lb. test to pull up an 80 lb. clear mono line made by Eagle Claw (available at Walmart). My question is how UV resistant is the 80 lb. clear Eagle Claw line? How will it hold up to the weather and abrasion? I can't find detailed info on the web. Good news is that it is nearly invisible against the sky and I may try to mist a little spray paint on it to cover the sheen. Anyone try this?

The slingshot took about 6 or 7 tries to get the limb I wanted and then after pulling the 80 lb. line up, I attached a plumb weight (about 8 bucks from Lowes), pulled that all the way up to the limb, then lowered it so it would come straight down and not over other limbs. Pulling the plumb weight up I noticed it tended to catch on the bottom of limbs as it rose because the top of the plumb is not tapered, so I came up with a fix; I took a dried out marking pin and cut off about 1 inch of the rounded tip at the rear of the pen and drilled a hole in the middle of the tip large enough to pass the line through. I removed the line from the plumb, ran it through the tip of the pin body and reattached it to the plumb with the tapered end of the pen body facing up. This formed a "nose cone" on top of the plumb and it was easily pulled up through the limbs without catching any. You can repeat this process for the other end of the line so your line is only over the one branch at the top with both ends of your line coming straight down. I my case it makes hiding the line against the trunk very easy.

Any help on the line specs and any suggestions for better line from you antennas guys or anglers is appreciated.

Jim, WB4ILP

32692. Trying to find cause of high SWR on 2m Yagi

Yahoo group: ham-antennas (2014)
Date: 2014-06-09 20:42:50 UTC
From: rob@...
Topic: 32692 Message: 32692

I built a 4-element Yagi (dipole driven element, 1/2 wavelength coax balon so the two sides are fed 180 degrees out of phase). When I put an MFJ259B on it, even with the reflector and directors removed, I couldn't find an SWR below about 1.9 anywhere near its nominal resonant frequency. The DEs are 6mm aluminum clamped w/5/16" screws into butt connectors soldered to 1/2" wide strips of brass and glued to a piece of plexiglass in the 1-14" PVC boom. Feed line is LMR240. The brass strips on each side are separated by about 1/4".

I tested it a few weeks ago and got very promising results. Going into a canyon, it gave a much better FM signal than an X50 mounted about 25' higher. I thought I was good to go. Not so much.

I took it out yesterday for a public service event, and found that of two HTs that I took, only one (Wouxun UVD1-P) would work. The Yaesu VX-6R wouldn't, and I assume it was balking at an SWR around 2.0. I'll be setting it up and testing on both radios while dropping power, removing the balun, various elements, etc. but don't expect to learn much, other than the VX-6 isn't happy.

Any ideas out there why a simple dipole wouldn't have a clear resonance point with low SWR? I'll try to get some pictures up in the files section.

Thanks,
Rob K6RGI

Good idea on the plumb line. I have used a large metal Nut and a wrench
also as a drop weight.
"nose cone" idea would work for them also.

32694. Re: Portable end-fed wire antennas

Yahoo group: ham-antennas (2014)
Date: 2014-06-09 22:57:09 UTC
From: wa1rkt@...
Topic: 32619 Message: 32694

OK, here are some results of some measurements I took with an MFJ-269 analyzer (the old one).

Antennas connected from the top rear roof of the 23-foot motorhome to a tree out in the yard, sloping upwards to a height of around 25-30 feet.

Antenna 1: 32.5 ft
Freq 4 MHz, R=2, X=92, SWR=>31
Freq 5 MHz, R=7, X=53, SWR=15.1
Freq 6 MHz, R=21, X=26, SWR=3.0
Freq 7 MHz, R=108, X=54, SWR=2.7
Freq 8 MHz, R=19, X=83, SWR=10.9
Freq 9 MHz, R=8, X=57, SWR=16.7
Freq 10 MHz, R=5, X=42, SWR=20.8
Freq 12 MHz, R=4, X=23, SWR=20.3
Freq 14 MHz, R=4, X=9, SWR=17.1
Freq 16 MHz, R=4, X=0, SWR=12.0
Freq 18 MHz, R=10, X=14, SWR=5.6
Freq 20 MHz, R=17, X=12, SWR=3.1
SWR dips:
6.572 MHz (1.1)
19.75 MHz (2.9)
33.94 MHz (2.1)

Antenna 2: 50 ft
Freq 3 MHz, R=3, X=113, SWR=>31
Freq 4 MHz, R=15, X=47, SWR=6.6
Freq 5 MHz, R=151, X=151, SWR=5.9
Freq 6 MHz, R=16, X=117, SWR=19.8
Freq 7 MHz, R=4, X=77, SWR=>31
Freq 8 MHz, R=2, X=57, SWR=>31
Freq 9 MHz, R=2, X=43, SWR=>31
Freq 10 MHz, R=3, X=32, SWR=>31
Freq 12 MHz, R=7, X=11, SWR=8.3
Freq 14 MHz, R=23, X=15, SWR=2.9
Freq 16 MHz, R=6, X=4, SWR=10.4
Freq 18 MHz, R=3, X=7, SWR=17.0
Freq 20 MHz, R=3, X=23, SWR=16.0
SWR dips:
4.554 MHz (1.1)
13.426 MHz (2.1
22.930 MHz (2.6)
31.793 MHz (2.0)

For the record, these readings are miles and miles away from the modeling I did.

Someone said I needed a 9:1 unun, but that doesn't look like it'll do any good... maybe a 1:9 or a 1:4...

Rick
Why don't you turn that antenna into a trap inverted L?
Use the dimensions for half a W3DZZ which will make a total length of 54 foot.
You can feed it with 50 ohms at the bottom of the vertical. put the trap in at about 32.4 feet . Even if the vertical leg is only 20 foot or so I think you will find it works pretty well and you will get good SWR on all bands.
I have been making one here. started off with the vertical section at about 22 foot but now I have it up at40 foot and I have also put a 80 metre trap in to cover 160 metres.
On the higher bands you will get some gain too!

Well Jim, I used to use similar line, first to support a 5/8ths wavelength CB vertical (the roof of my mobile home was the ground plane). Later used that same 23 foot vertical wire as my Novice antenna with a pi section tuner in the shack.

The line held up well for more than a year between replacements. That in a mobile home park that did NOT allow antennas. Just needed a nice line of ash trees on the lot.

Subject: RE: [ham-antennas] Vertical Antenna in Limited Area

Using a slingshot and a ½ ounce fishing sinker I have managed to get a 6 lb. test mono line into a very good tree limb in my back yard at about 50 feet. I used the 6 lb. test to pull up an 80 lb. clear mono line made by Eagle Claw (available at Walmart). My question is how UV resistant is the 80 lb. clear Eagle Claw line? How will it hold up to the weather and abrasion? I can't find detailed info on the web. Good news is that it is nearly invisible against the sky and I may try to mist a little spray paint on it to cover the sheen. Anyone try this?

The slingshot took about 6 or 7 tries to get the limb I wanted and then after pulling the 80 lb. line up, I attached a plumb weight (about 8 bucks from Lowes), pulled that all the way up to the limb, then lowered it so it would come straight down and not over other limbs. Pulling the plumb weight up I noticed it tended to catch on the bottom of limbs as it rose because the top of the plumb is not tapered, so I came up with a fix; I took a dried out marking pin and cut off about 1 inch of the rounded tip at the rear of the pen and drilled a hole in the middle of the tip large enough to pass the line through. I removed the line from the plumb, ran it through the tip of the pin body and reattached it to the plumb with the tapered end of the pen body facing up. This formed a "nose cone" on top of the plumb and it was easily pulled up through the limbs without catching any. You can repeat this process for the other end of the line so your line is only over the one branch at the top with both ends of your line coming straight down. I my case it makes hiding the line against the trunk very easy.

Any help on the line specs and any suggestions for better line from you antennas guys or anglers is appreciated.

G3VIR>> "Why don't you turn that antenna into a trap inverted L?"

Good evening, Roley.

Mostly because it's not intended only for the ham bands. It's also (one might say primarily) intended for use on CAP and MARS frequencies, some of which are a fair distance from the nearest ham band.

I used 33 ft for the wire length.

dips:

6.97 MHz, R = 50 SWR=1
22.5 MHz, R = 108, SWR = 2.24
~30 Mhz, not reliable. The m.h. had hefty currents here.

> Antenna 2: 50 ft
> Freq 3 MHz, R=3, X=113, SWR=>31
> Freq 4 MHz, R=15, X=47, SWR=6.6

> 4.554 MHz (1.1)
> 13.426 MHz (2.1
> 22.930 MHz (2.6)
> 31.793 MHz (2.0)

4.9 MHz, R = 40, VSWR=1.3
13.24 MHz, R = 220, VSWR=4.5 !Both this and the 16.9MHz resonance
16.9 MHz, R = 220, VSWR=4.5 !involved big currents in motorhome
23.7 MHz, R = 137, VSWR=2.8 !some currents in mh.
30 MHz, did not simulate (lazy)

As for the measured Zs, I have no agreement with them. For example, in the 50ft case, I have R~200-500 between 14 and 16MHz. The X values have not much agreement at all. (Ignoring sign, of course).

The moral may be that an MFJ analyzer is not very reliable for measuring Z, i.e. it is not a $10K vector network analyzer.

And my model of the m.h. is weak and may even suck.

** Conclusion from my modelling, the m.h. is definitely involved.

> For the record, these readings are miles and miles away from the modeling I did.
>
> Someone said I needed a 9:1 unun, but that doesn't look like it'll do any good... maybe a 1:9 or a 1:4...
>
> Rick WA1RKT

Maybe I'll try to cobble a new m.h. model.

I think the MFJ VSWR may be reliable, but the Z is not. (I have a 259B and am wondering about it now. I don't have any standards to calibrate it or even get confident in it. I suppose some lengths of coax or even some R's and C's soldered into a 239 plug might be handy.)

I'd give the 33 ft wire a smoke test on 40m.

AB3NR>> "The moral may be that an MFJ analyzer is not very reliable for measuring Z, i.e. it is not a $10K vector network analyzer."

How confident are you that the modeling software is accurate? I'm not referring to the motorhome model, which may or may not be accurate, but the modeling software itself?

I'm no fan of MFJ but their antenna analyzers do seem to have a reasonably good reputation from the things I've read. I can certainly accept their measurements to be off by 10 or 20 percent but not by 100 percent or more. I would think that owners would be squawking all over the review sites if that happened and I haven't seen that.

Thanks Don ! I feel the $8 bucks for the plumb bob was a good investment as I have at least 2 trees that show potential to be my version of a Rohn tower. The plumb bob has a pointed bottom and enough weight to slip easily through limbs on it's way down and the nose cone helps on the way up. In my previous QTH's I had to get by with antennas at 15' or so but they did work. 50 feet to me is like the summit of Everest.

I would like to tell others in the group that antennas at low altitude do work and you can make lots of contacts. In my job at Alpha Delta I speak with customers who think they can't enjoy our hobby because they can't get an antenna up at 35'. Height is good but low antennas can give you lots of ham radio excitement.

Oh yes, they do work. But like you say higher the better. I lived in
Florida beach community for 40 years with no high trees.
Vertical monopoles worked well, as did slopers from ground to top of a pole
mounted on the roof.
Actually a 20 foot pole on the roof with 3 wires down to the ground to
simulate a tower and the coax run to the top of the pole. I made a W9INN
sloper with 40 meter main, coil and wire for 80 and coil and wire for 160.
I had a 20 meter wire also but at 90 degrees. With 100 watts and a small
homebrew tuner I worked WAS and WAC on 80, 40, 20.
Here in Ecuador we also have few high trees on the coast. But we have 10 to
12 meter bamboo poles that cost $7 each. So my fan dipole 40 to 15 is up 35
feet on top of a small hill which put it abut 100 foot above surrounding
land. Half mile from Pacific beach and surrounded by large shrimp ponds,
the ground is very reflective, WET. So I get good reports from my 100 watts
and when propagation is good from the QRP rigs.

Fairly confident. It's just NEC-2 with a graphics wrapper (xnec2c) on it.
I could try it by running the original LLNL Fortran source code with the
same card deck, if you're doubtful about the C++ translation I used. (It's
fairly standard stuff on the Linux side of things, nec2++, so-called.)

I'm less confident of my modelling skills.

I can send you the input card deck, if you wish, or LLNL NEC-2 printout.

I've got a better mh model now, (wire frame, 3-D, on 1/2 meter grid).
It has a lot of segments (several thousand). Takes a couple
of minutes per point, so several hours maybe for a "big" run. Shades
of 1985! At least I own the "Vax" now.

I'll try running it for the 33 ft case tomorrow. Sleepy time here now.

Hmm. Maybe I'll try an overnight run. I'm worried about the
computer overheating if run too much by day. (It sounds like a wind
tunnel right now when running the model. Loadfactor = 1.0).

>I'm no fan of MFJ but their antenna analyzers do seem to have a reasonably good reputation from the things I've read. Maybe it's broken? 269s have a way of frying themselves if used
incorrectly on 70cm, so I hear.

The X values you measured didn't seem realistic over the whole frequency
spectrum. But your test environment is unknown to me.

The MFJs seem to work OK when X~=0., but I don't think they really have
an impedance bridge in them, I think they are *calculating* |Z|, then R
and X from VSWR by directly measuring forward and reverse voltages as a
proxy for power. Hence the reason they don't have the sign of X, always
showing it positive. (Not a feature unique to MFJ analyzers, of course.)
As I said, it's not a VNA. I haven't seen a schematic for one, though,
so there could be anything in there. VSWR is more reliable, I'm confident.

We have to face the fact that many hams don't know impedance from their
elbows, and VSWR is the defacto gold standard.

Well Jim, I used to use similar line, first to support a 5/8ths wavelength CB vertical (the roof of my mobile home was the ground plane). Later used that same 23 foot vertical wire as my Novice antenna with a pi section tuner in the shack.

The line held up well for more than a year between replacements. That in a mobile home park that did NOT allow antennas. Just needed a nice line of ash trees on the lot.

I removed the line from the plumb, ran it through the tip of the pin body and reattached it to the plumb with the tapered end of the pen body facing up. This formed a "nose cone" on top of the plumb and it was easily pulled up through the limbs without catching any. You can repeat this process for the other end of the line so your line is only over the one branch at the top with both ends of your line coming straight down. I my case it makes hiding the line against the trunk very easy.

Any help on the line specs and any suggestions for better line from you antennas guys or anglers is appreciated.

Jim, WB4ILP

Halfwave coaxbalun is used in a folded dipole (with nominal impedance from 300 ohms lowered to 200 ohms from reflector and director) ... not on a straight dipole

From: p_chap@...
Topic: 32632 Message: 32706

Good morning Jim:

I have used various types of rope, all with the same result....less than a year and done, then start over again. I went with the black Dacron antenna rope sold by Wireman and others several years ago and have not looked back. Five to ten years can be expected, which, in a way creates a problem. It can grow into the tree limbs.

There are many ways to do the same thing i.e. get an antenna in the air. I mount a reel on an elbow support slingshot, fire 10 lb test line with a half ounce sinker and a few inches of pink mason twine to find it easy, cut off the sinker, pull back with mason twine, then hoist the rope. (1/4 inch black dacron, about 1200 lb strength about $70 per 500 ft spool.) When I have enough rope to touch the ground on both sides of the limb, (and want to run two antennas in different directions.) I then cut the rope, attach a screw down carabiner, (not spring loaded,) and two MARINE GRADE (about $10 each) swivel pulleys specified for 1/4 inch rope. Using two 500 ft spools of rope, run the rope through the pulleys, tie off to the base of a tree, and hoist the assembly. When there is enough rope to hit the ground on both sides of the pulleys, cut the ropes and attach the antennas.

This method uses a lot of rope, but if you have a $70 balun in the air, it is cheap insurance. If rope number one grows into the tree, you can still lower and raise each antenna individually. Ideally one should drop the whole assembly once a year to check and clean the pulleys as needed. My project doing this is a little slow, but about half way there.

OK Jim, now I have to dig back into my dim memory...
Had one actual failure in the eight or nine years of use. A nasty windy storm did it in. Had to go up on the trailer roof and play fisherman, lofting a sinker up into the tree. Folks walking by got a show... "that guy's a nut!" But nobody ever turned me into the park management.
Take note though, the wire, 18ga. copperweld, was kept taught, so there was not too much play to handle the violent tree sway, except in the line's ability to stretch.
Other times I swapped out the line when I pulled the wire down to transition from the roof mounted CB coil to a ceramic feed through when I went ham. Line had some abrasion where it went over the limb, but was still serviceable.
I'd probably feel comfortable swapping it out every year or so. Or, you might look into grass cutting line, some of that stuff's pretty heavy, I'd do pull tests on both.

Well Jim, I used to use similar line, first to support a 5/8ths wavelength CB vertical (the roof of my mobile home was the ground plane). Later used that same 23 foot vertical wire as my Novice antenna with a pi section tuner in the shack.

The line held up well for more than a year between replacements. That in a mobile home park that did NOT allow antennas. Just needed a nice line of ash trees on the lot.

Subject: RE: [ham-antennas] Vertical Antenna in Limited Area

Using a slingshot and a ½ ounce fishing sinker I have managed to get a 6 lb. test mono line into a very good tree limb in my back yard at about 50 feet. I used the 6 lb. test to pull up an 80 lb. clear mono line made by Eagle Claw (available at Walmart). My question is how UV resistant is the 80 lb. clear Eagle Claw line? How will it hold up to the weather and abrasion? I can't find detailed info on the web. Good news is that it is nearly invisible against the sky and I may try to mist a little spray paint on it to cover the sheen. Anyone try this?

The slingshot took about 6 or 7 tries to get the limb I wanted and then after pulling the 80 lb. line up, I attached a plumb weight (about 8 bucks from Lowes), pulled that all the way up to the limb, then lowered it so it would come straight down and not over other limbs. Pulling the plumb weight up I noticed it tended to catch on the bottom of limbs as it rose because the top of the plumb is not tapered, so I came up with a fix; I took a dried out marking pin and cut off about 1 inch of the rounded tip at the rear of the pen and drilled a hole in the middle of the tip large enough to pass the line through. I removed the line from the plumb, ran it through the tip of the pin body and reattached it to the plumb with the tapered end of the pen body facing up. This formed a "nose cone" on top of the plumb and it was easily pulled up through the limbs without catching any. You can repeat this process for the other end of the line so your line is only over the one branch at the top with both ends of your line coming straight down. I my case it makes hiding the line against the trunk very easy.

Hi there fellow hams. My question is. I am putting up a 3 element 20 meter monoband yagi. Hy gain 203BA. I am trying to figure out what the best length of davis bury flex coax would be. My calculations are 43' 9" or 128' 3" . Would anyone have a formula or just advise the perfect length of coax for this installation. I am using a balun design 1:1 5KW choke balun. 73

Properly adjusted for a good 50 ohm match at the antenna, the length of the coax is not a factor. Shorter would be better due to slightly (very slightly) lower losses, but the difference in actual loss between 50' and 150' would not be noticeable to we mere humans

I have never had any issues with lengths of coax other than keep it as short as possible. Avoid off lengths where the impedance can be transformed.

32712. RE: [ham-antennas] Vertical Antenna in Limited Area

Yahoo group: ham-antennas (2014)
Date: 2014-06-10 17:59:39 UTC
From: jim burns
Topic: 32632 Message: 32712

Hi Paul,

The pink mason twine is a great idea. I couldn't believe how difficult it was to find the 6 lb. line after I got it over the limb. I think I'll go with the pulley as you suggested. My 80 lb. line was up since back in the winter and it had started to grow into the limb and it took a lot of tugging on one end and then the other to free it. I am thinking of using a small diameter stainless steel rope with an insulator at the pulley end and using it as a vertical antenna. Directly under the pulley is my chain link fence which with my neighbor's fences is probably a total of about 600 feet long. I would feed the vertical against the fence as a counterpoise. Probably not a great antenna but it is convenient.

It occurred to me that a piece of tubing over the rope or other hoisting line at the pulley end where the line goes over the limb would prevent the line from growing into the limb.

To the Group.

I've tried using a 1/2 oz lead weight on a spinning reel, which works well for getting the weight over the appropriate limb. However, I have found sometimes a 1/2 oz weight is not heavy enough to overcome the friction of the cord on the limb and pull the line back down to earth.

I ended using a 1oz lead weight which works much better. I just shot a 1oz lead weight attached to 1/16" diameter cotton cord over a 60 foot high limb in a pine tree for my 2 meter J-Pole antenna, on the third try.

Also, use a new a rubber band for the sling. The rubber loses elasticity quickly. An old rubber band will negatively effect the performance of the sling shot.

Some stores sell a replacement rubber sling that is stronger then other slings. The stronger rubber is usually colored red. The lighter rubber is usually yellow.

Built my own for $30.

4" X 2' air chamber, 1.25" ballcock, PSI gauge, air valve, check valve, into a 4' x 1.5" launch tube.

Made up 3" x 1.5" pvc pieces with end caps, swivel fishing catch. 15lbs test mono line, open bailer real,

two stainless hose clamps.

Over a 100' range with 50psi. No more slingshots, fishing poles or bows.

This gets over the largest trees in this area.

I have pics if anyone is interested.

Blast off !

I want to build one

What are you shooting what 4" thing are you putting in the launching?

Waffle ball with the3 fishing line attached?

Send pictures

Subject: [ham-antennas] Projectile launcher

Built my own for $30.

4" X 2' air chamber, 1.25" ballcock, PSI gauge, air valve, check valve, into a 4' x 1.5" launch tube.

Made up 3" x 1.5" pvc pieces with end caps, swivel fishing catch. 15lbs test mono line, open bailer real,

two stainless hose clamps.

Over a 100' range with 50psi. No more slingshots, fishing poles or bows.

This gets over the largest trees in this area.

I have pics if anyone is interested.

Blast off !

Tennis ball works superb

http://www.antennalaunchers.com/antlaunching.html

many info about launchers, comparing different designs (different valves, chamber-sizes etc.)

very informative

32723. Re: AW: [ham-antennas] Trying to find cause of high SWR on 2m Yagi

Yahoo group: ham-antennas (2014)
Date: 2014-06-10 21:31:45 UTC
From: rob@...
Topic: 32692 Message: 32723

Thanks Sigi, but I'm a bit confused - The coax balun is only intended to feed the two halves of the dipole out of phase. What I forgot to mention originally is I've got a hairpin match on it (~20 cm of 14 AWG solid copper) which lowered the SWR a little bit. I did model it with MMANA-GAL, stating it would be a hairpin match. The model said SWR should be 1.2 to 1.4 from ~145 to 147 MHz. I suppose I could take the coax balun off and put an ugly balun in the feedline as a first test.

On antennalaunchers dot com you will find a complete list what you need

Sprinklervalve converted to pneumatic action is the main part :-)

Air chamber and barrel plus some elbows (makes the launcher more compact as mounting all in a row)

Good luck in building

Dg9bfc

Sigi

Ps I ordered my sp. valve direct from manufacturer in italy ... way cheaper as buying from ANY garden shop or other reseller ... or in other words ... got two valves for the price of one :-)

From: siegfried jackstien
Topic: 32692 Message: 32725

Coax balun not only inverts phase but also lifts up impedance to 4 times nominal value (50 ohms to 200 ohms)

What about converting your hairpin match to a gamma match?!? ... no balun needed then ... or just a tiny bit (ugly balun style)

Impedance can be controlled then with the gamma slider and the antenna should work superb

Love to build one orders are $ 120.00 - $ 150.00

After all the reading I can□t understand how the trigger works. It looks like it lets air in to the atmosphere, and not from the charged area to the lunch tub?

What□s wrong with a ¼ ball vale?

Richard

From: siegfried jackstien
Topic: 32632 Message: 32730

It is easy how they work

You have a diaphragm that is controlling the air flow

Diameter of that (and of the chamber above it) is bigger as the exhaust diameter (that then goes to the barrel)

In closed condition the bigger diameter of the chamber above the exhaust securely holds the valve closed (bigger area means bigger force downwards)

Now if you let the pressure out of the upper chamber above the diaphragm the valve "pops open" in a short time

That popping effect is what makes the air flow in a high speed towards the barrel (and the shoots out the tennis ball)

If you look on antennalaunches.com it is well explained

And ... if you look on the building instructions for the "darn fast turbo" launcher there also is explained how these things work

Dg9bfc

Even then only with certain types of antennas and line matching systems
(Baluns, Antenna tuners etc)....

Subject: AW: [ham-antennas] Re: Projectile launcher

It is easy how they work

You have a diaphragm that is controlling the air flow

Diameter of that (and of the chamber above it) is bigger as the exhaust diameter (that then goes to the barrel)

In closed condition the bigger diameter of the chamber above the exhaust securely holds the valve closed (bigger area means bigger force downwards)

Now if you let the pressure out of the upper chamber above the diaphragm the valve "pops open" in a short time

That popping effect is what makes the air flow in a high speed towards the barrel (and the shoots out the tennis ball)

If you look on antennalaunches.com it is well explained

And ... if you look on the building instructions for the "darn fast turbo" launcher there also is explained how these things work

The manual states 150' minimum of RG213 regardless of distance from shack. It is in the manual. And beeline it or not I decided to try 150' of LMR400 and the swr for the antenna was impacted negatively. By the way, the antenna is a good performer for me but then again one could argue how good is it really.

Hi Bill,

Thanks for the info. My slingshot is 5 to 10 years old so I guess I need a rebuild. Seriously, I thought it seemed weaker last time I used it.

Thanks again.

Jim, WB4ILP

From: ham-antennas@yahoogroups.com [mailto:ham-antennas@yahoogroups.com]
Sent: Tuesday, June 10, 2014 3:00 PM
To: ham-antennas@yahoogroups.com
Subject: Re: AW: [ham-antennas] Vertical Antenna in Limited Area

To the Group.

I've tried using a 1/2 oz lead weight on a spinning reel, which works well for getting the weight over the appropriate limb. However, I have found sometimes a 1/2 oz weight is not heavy enough to overcome the friction of the cord on the limb and pull the line back down to earth.

I ended using a 1oz lead weight which works much better. I just shot a 1oz lead weight attached to 1/16" diameter cotton cord over a 60 foot high limb in a pine tree for my 2 meter J-Pole antenna, on the third try.

Also, use a new a rubber band for the sling. The rubber loses elasticity quickly. An old rubber band will negatively effect the performance of the sling shot.

Some stores sell a replacement rubber sling that is stronger then other slings. The stronger rubber is usually colored red. The lighter rubber is usually yellow.

Bill

32741. MFJ-269x Antenna Analyzer Reliability and Accuracy

Yahoo group: ham-antennas (2014)
Date: 2014-06-11 13:28:40 UTC
From: wa1rkt@...
Topic: 32741 Message: 32741

In the conversation on "Portable end-fed wire antennas", a question was raised about the reliability and accuracy of the MFJ-269 series of antenna analyzers. In particular, measurements have been made that are widely divergent from what the models say they should be.

What has your experience been with those analyzers? Are you reasonably confident in their accuracy, and conversely, have you seen anything that would make you suspect that their accuracy is off?

Rick WA1RKT

32742. Re: [ham-antennas] MFJ-269x Antenna Analyzer Reliability and Accuracy

Yahoo group: ham-antennas (2014)
Date: 2014-06-11 14:34:00 UTC
From: Artek Manuals
Topic: 32741 Message: 32742

I think QST did a comparative article on several of the antenna analyzers in the last couple of years...Setting asides the long standing MFJ (otherwise known as Mississippi's Finest Junk) tradition of cheap construction, shoddy workmanship and almost no useful service documentation as I recall most of the analyzers including the MFJ did reasonably well in the 7 to 21 MHz range and accuracy dropped off considerably at the low and high ends of the HF amateur spectrum. I have an AEA unit that while it has excellent workmanship, it to suffers the same fate on 160M as the others.

One useful but tedious approach is make a set of correction factors using high tolerance fixed R, L and C
You can simulate complex impedance this way quite accurately especially at 80 and 160M where lead inductance and stray C are 2nd order affects. I once took a set of measurements on a 160M antenna with my AEA unit then went back to bench and using a variable cap , resistor , and inductor recreated the readings , measured the R, L & C and computed the actual complex impedance of the antenna that way then designed a matching network based on those numbers rather the actual reading from the AEA unit.

Another problem with most analyzers the MFJ included is that in the presence of strong local AM broadcast stations, these fields get picked up and cause erroneous errors on the analyzer as well.

The moral is it is never easy and detailed knowledge of the instruments limitations at any given frequency are worth the effort inthe long run

I will look and see if I can find the QST article

32745. Hy Gain 14AVQ Vertical

Yahoo group: ham-antennas (2014)
Date: 2014-06-11 15:47:24 UTC
From: ve1rsm@...
Topic: 32745 Message: 32745

Looking for some assistance. If someone has a 14AVQ Hy Gain Vertical with the optional 40 meter trap I would like some measurements and assistance in erecting one correctly, on the CW bands.

A friend of mind Mike) who had a stroke a while back and has limited speech and use of his hands recently purchased the 14AVQ at a ham fest.

He has the following traps (40, 20, 15 and 10 meters) along with the tubes and manual. There is a bit a difference in the measurements of two of the tubes which differ from the manual, but I am sure we can work around that if we can get some assistance.

We have tried to erect it according to the 14AVQ manual, with adding the optional 40 meter trap first in line, followed by the 10, 15 and 20 meter traps, as indicated in the manual.

We had very poor swr readings and nothing close to any amateur bands.

We then erected the antenna according to the manual, this time not using the 40 meter trap at all, we had an acceptable SWR reading on 20 meters but nothing at all on 10 or 15.

Any assistance would be greatly appreciated, otherwise it will be trial and error to try and get this antenna erected and working on the CW bands.

Mike only works CW due to his limited use of hands and his problem speaking.

Hi Bob – I am not very well acquainted with oyur antenna however, I typically refer to the antenna from the base or round up – as I read your letter I am wondering if you may have missed one thing in the directions – the 10 meter coil is near the base – then 15, then 20 etc – as you go up the antenna mast – is this the way you are assembling yours – Gud Luk – 73 Dave / WØDR

Subject: [ham-antennas] Hy Gain 14AVQ Vertical

Looking for some assistance. If someone has a 14AVQ Hy Gain Vertical with the optional 40 meter trap I would like some measurements and assistance in erecting one correctly, on the CW bands.

A friend of mind Mike) who had a stroke a while back and has limited speech and use of his hands recently purchased the 14AVQ at a ham fest.

He has the following traps (40, 20, 15 and 10 meters) along with the tubes and manual. There is a bit a difference in the measurements of two of the tubes which differ from the manual, but I am sure we can work around that if we can get some assistance.

We have tried to erect it according to the 14AVQ manual, with adding the optional 40 meter trap first in line, followed by the 10, 15 and 20 meter traps, as indicated in the manual.

We had very poor swr readings and nothing close to any amateur bands.

We then erected the antenna according to the manual, this time not using the 40 meter trap at all, we had an acceptable SWR reading on 20 meters but nothing at all on 10 or 15.

Any assistance would be greatly appreciated, otherwise it will be trial and error to try and get this antenna erected and working on the CW bands.

Mike only works CW due to his limited use of hands and his problem speaking.

Bob,
I had 2 14AVQ's over the years. I still have the instruction manuals. But never heard of an optional 40 meter trap. The 14 AVQ worked on 40 - 10 meters but only had traps for 20, 15, and 10. The overall length with top hat worked for 40. They did make this antenna over a long period of time. And I think they may offer it today, and may be a re-design from when I had mine. The ones I had were from the early 70's.

From: wa1rkt@...
Topic: 32619 Message: 32748

Tried running a 52-ft counterpoise wire at about 7 feet elevation from the 23-foot motorhome frame near where the coax connects, to a convenient tie-off point, running in roughly the opposite direction to a 50-foot radiator sloping up to about 25 feet high up a tree. The counterpoise didn't make a significant difference in the MFJ analyzer measurements, in fact above about 7 MHz it made no measurable difference at all, i.e. any difference can be accounted for by the fact that frequency on the MFJ-269 can't be set very accurately.

Below 7 MHz here are the measurements with and without the counterpoise wire.

Numbers are: Freq(MHz) / Impedance / Phase(deg) / SWR. First group is with the counterpoise and 2nd group is without.

2 / 203 / 90 / >31
3 / 110 / 88 / >31
4 / 49 / 41 / 2.2
5 / 193 / 47 / 5.5
6 / 119 / 83 / 22.2
7 / 78 / 87 / >31

2 / 208 / 89 / >31
3 / 115 / 87 / >31
4 / 59 / 65 / 4.7
5 / 203 / 37 / 4.8
6 / 123 / 81 / 17.9
7 / 80 / 87 / >31

Doesn't look like the counterpoise brings anything to the table over the end-fed wire working against the motorhome body, except perhaps a different radiation pattern.

The RigExpert ones do look pretty good... call me paranoid if you want, but I think I'm going to hold off on buying any big-ticket items from Ukraine until whatever plans Putin and his crew have in mind play themselves out.

Anyway, I *_have_* an MFJ-269 (borrowed) at the moment and am just looking to get an opinion from experienced users about that particular device's accuracy since I'm seeing things, reported in the "Portable end-fed wire antennas" discussion, that diverge rather widely from the models.

I own a MFJ-259B and I agree that in the mid range of HF it is reasonably accurate but mine will not work on 160m. It shows my sloper to be at >25:1 SWR throughout the band. When I run my K3 EZ program swr scan it is like 1.1:1 at 1.8 MHz going up to 4:1 at top of the band. It is inaccurate on 6m by a couple 100 kHz.

The key to maintaining the modest accuracy is to keep the batteries fresh. It takes a lot of AA batteries and I am replacing them at least every six months. If the voltage drops below a certain level the accuracy is completely gone.

I wouldn't buy another one of these units but I am ok with it for general use. I think every ham shack (for HF or DX enthusiasts) should have an antenna analyzer of some nature.

I solved the battery problem by taking the 12 volt gelcell from a dead ups and dropping it into the charger/carrier bag that was left over from my old battery operated Airline B&W Tv .

cut the wire off of a dead wall wart that had the correct size plug and connected it to the wire that used to plug into the TV .

150' minimum coax length is ridiculous...I had a ta-33m up on my 40' tower at my old qth and ran 70' to the shack. the swr was excellent on most bands exept 10 meters where it was min 1.7:1 but that was tuned easily. So the shorter the better just avoid odd multiples on the bands you work.

Dave,

Feedline can be used as an impedance transformer

Impedance = square root of impedance of feedline multiplied by impedance of antenna.

So half wave lengths are ideal. However as I said before short as possible always worked for me

It would seem that you would want the coax to be as short as possible. To have a requirement from a beam manufacturer, that the coax be a minimum length of 150 feet seems incorrect (crazy actually). Using 150 feet of coax will give you at least a DB and a half of loss even with the best coax. Dave. WA6TXU.

32764. Re: [ham-antennas] New yagi installation question

Yahoo group: ham-antennas (2014)
Date: 2014-06-11 21:21:38 UTC
From: Artek Manuals
Topic: 32708 Message: 32764

Or said another way

They couldn't achieve a low enough SWR and meet other design goals (BY DESIGN) so they rely on the losses in 150 feet of coax to flatten the SWR curve (BY DESIGN)..what a chuckle

That's probably more like the thing. Like the comet cha 250 it achieves low swr on a lot if bands due to the lossy 6:1 transformer. Poor really but that's the reality.

I think they probably designed it that way for the three elements on 40m, but not sure. It works great for me so I am not complaining.

Billy
What you say is true of feed-line when _*mismatched*_. This will indeed produce a different output impedance as a function of the feed line length. By varying the line length you will find certain output impedance's that your built-in tuner can handle and conversely certain impedance's that your built in tuner can not tune. Assuming the lossless case for the sake of simplicity the SWR on the feed-line does not change as a function of length. The SMITH CHART is basically built around this principle

However a feed-line terminated in its characteristic impedance (i.e 50 ohm termination for 50 ohm coax) transforms nothing and will always show 50 ohms at the far end regardless of length. Assumes lossless coax which for this argument is close enough

I think they pull the same stunt on the Hi-tower vertical. Don't they specify at least 100' (or more) of coax for that too?

32769. Re: [ham-antennas] New yagi installation question

Yahoo group: ham-antennas (2014)
Date: 2014-06-11 21:56:36 UTC
From: Keith Heimbold
Topic: 32708 Message: 32769

I don't know about that particular antenna. The S33 has a short boom for 40m (24') for a three element antenna and shortened elements as well (around 40'). I am not sure why they designed it the way they did.

The antenna works well for my purposes and it had been great on all bands it is designed to work on. I am sure it is a compromise antenna but still performs well and I have worked a lot more DX on 40m than I did before.

Keith

>>>>> It would seem that you would want the coax to be as short as possible. To have a requirement from a beam manufacturer, that the coax be a minimum length of 150 feet seems incorrect (crazy actually). Using 150 feet of coax will give you at least a DB and a half of loss even with the best coax. Dave. WA6TXU.

On Wed, Jun 11, 2014 at 09:34:08AM -0700, wa1rkt@... [ham-antennas] wrote:
> Tried running a 52-ft counterpoise wire at about 7 feet elevation from the 23-foot motorhome frame near where the coax connects, to a convenient tie-off point, running in roughly the opposite direction to a 50-foot radiator sloping up to about 25 feet high up a tree. The counterpoise didn't make a significant difference in the MFJ analyzer measurements, in fact above about 7 MHz it made no measurable difference at all, i.e. any difference can be accounted for by the fact that frequency on the MFJ-269 can't be set very accurately.

So the counterpoise is just another wire attached to the MH, and you are still feeding the MH skin with one leg of the coax? I thought the purpose of the CP wire was to get the MH disconnected from the antenna feed.

In my model, I use a right-handed coordinate system, X, Y, Z.
The X axis emerges from the "screen", + towards the viewer.
The Y axis lies in the screen, + rightwards.
The Z axis lies in the screen, + upwards.
(In "mathese", let xhat, yhat and zhat be unit vectors such that xhat=(1,0,0), yhat=(0,1,0), zhat=(0,0,1). Then xhat CROSS yhat = zhat, yhat CROSS zhat = xhat, and zhat CROSS xhat = yhat)
You know this, but we may have spectators who don't.)

The motorhome is oriented so that its length, or long axis, is parallel to the X axis, symmetric about the XZ plane. The wire radiator lies in the XZ plane. In other words, if the MH were being driven, it would go in the +X direction and the wire would trail behind it as if held aloft by a kite. The earth is the XY plane.

In either example below, I no longer understand where the wire or counterpoise are.

Do you have the facility (and desire) to compile and run a small C language program in a "text" window, and capture the output to a file suitable for input to your modelling software? Although used here on *n*x, it should be ANSI compliant and compile and run on just about anything with a C or C++ compiler. The program has no input, and writes on standard output. The output is a wireframe model of the motorhome, produced as a NEC2 input deck, with a wire, and minimal other cards to produce an executable NEC2 input deck as-is. Configuration is by changing #define statements within the program using a text editor such as vi.

> Below 7 MHz here are the measurements with and without the counterpoise wire.
>
> Numbers are: Freq(MHz) / Impedance / Phase(deg) / SWR. First group is with the counterpoise and 2nd group is without.

Truth will out... Now I see that your earlier post of readings, although called R and X, may really have been magnitude and phase. mag = hypotenuse(R,X), phase = arctan(X/R).

My modelling results were all in R and X where Z = R + jX

To calibrate frequency on any analyzer: fit it with a little "antenna", such as six inches of bare wire stuck in the center conductor of the output SO-239. Turn it on near (a few feet from) a receiver set to AM. A portable SWL receiver with a whip is very handy. You may want to retract the whip all the way. Tune analyzer to nominal frequency, then find it on the receiver. (Or vice-versa, tune in the radio, then sweep the analyzer freq setting until you get max scream.) You will know when you're on frequency! Receivers, if recent, are pretty good at this; verify them with WWV, naturally. My MFJ259B with digital display agrees very closely with what I see on a Grundig receiver. (I throw in some RF attenuation when doing this.)

I have heard of one or two people who had suspect MFJ-259/269's, whose readings did not make any sense. I don't know if it was a calibration issue or what. Other than that, I think these meters are fairly decent for what you paid for. Don't expect precision, don't expect good readings when you get far from 50 ohms, but otherwise, they aren't that bad.

Remember that the MFJ-269 has a setting to control "nominal" impedance. If someone has set it to 600 ohms and you use it on a 50 ohm system, its SWR readings won't look right to you until you reset that setting.

I suspect the biggest reason for difference between models and measurements, is in the models and modeling. Perhaps the models are incomplete (if it's anything other than a wire dipole or a vertical over a very good ground system, it might be). Some things model well; others do not, except that you can use them for comparative purposes if you take the absolute data with a big grain of salt. There are some structures that just do not model as well as we would like them to, when using NEC-based modeling programs.

Many people model the antenna but forget to include the feedline. You can load up a coax feedline with nothing on the end of it.

Another reason for measurement errors, is if there is some common-mode feedline radiation going on. If the readings change when you touch or approach the meter, then that is probably happening.

Andy

>> I thought the purpose of the CP wire was to get
>> the MH disconnected from the antenna feed.

That's not easy, with the way things are currently mounted. But yes, ultimately that's one objective. But it's intended more as an academic exercise than anything else, just to see how it acts... we won't often be able to deploy the antenna that way in the field and will usually be stuck with an end-fed wire tied to a nearby tree.

>> The motorhome is oriented so that its length, or long axis, is parallel to the X axis,

>> words, if the MH were being driven, it would go in the +X direction and the wire
>> would trail behind it as if held aloft by a kite.

Pretty much. The wire is connected at the top rear passenger-side corner of the motorhome body, and extends rearward and upward from there. The counterpoise wire extended from there forward along the body of the motorhome and then further to a total of 52 feet.

>> Truth will out... Now I see that your earlier post of readings, although
>> called R and X, may really have been magnitude and phase.

No, they were really R and X. I only started using magnitude and phase over the last couple of days, after I discovered how to set up the analyzer to output that... this is the first time I've used one of those analyzers and it didn't come with an instruction manual.

>> To calibrate frequency on any analyzer:...

I tried listening to the output of the analyzer on my IC-706 and it was close enough... when I mentioned that frequency on the MFJ-269 can't be set very accurately, I meant repeatability... you breathe on the tuning knob and it wanders on down the road by a few tens of KHz.

Thanks Sigi and Geoff (and Bill who PM'd), Seems to work ok now without the 1/2-wave coax balun. I did put a 5-coil ugly balun in the LMR-240 feedline to block common mode RF. The hairpin doesn't seem to make much difference. Need to borrow an analyzer to see what's there. MMANA says impedance should be 55.28+j3.24 (SWR = 1.12), but would like to confirm. As an alternative to a gamma match, I've seen references to "transformer baluns" that consist of two side-by-side 1/4-wave pieces of coax wired to raise or lower the apparent antenna impedance to 50 ohms. Haven't found details, and don't know yet what impedance is being currently being presented. We'll see . . ..

Put an atu at the base and it will tune near any length to any band

If you had used a longer radiator around 60 feet you would have resonance on 80

Add another 30 feet wire to another tree and you have resonance on 40m

We often use such a setup on fieldday (2 wires against mobile home)

And I also used it while on a camping lot :-)

With atu at the base your antenna should NOT be resonant on 80 as a quarterwave (otherwise high impedance on 40 and atu will not find a match)

So ... question is ... what you wanna do with your radiator?!? Monoband and resonant on that band? ... or multiband and easy to tune on any band??

With that in mind you can select to either use 27m and an atu ...

Or use 10 and 20m and feed it direct with coax

32776. Re: MFJ-269x Antenna Analyzer Reliability and Accuracy

Yahoo group: ham-antennas (2014)
Date: 2014-06-12 00:12:31 UTC
From: Ralph Javins
Topic: 32741 Message: 32776

Good morning;

The accuracy of the MFJ 259 and 269 Antenna Analyzers is reasonable. And they certainly do cover a very wide range. My RF Impedance Bridges are nowhere near being at all similarly portable.

One way to make a "self check" with them is to watch the impedance indicator meter or the digital display portion where the impedance (Z) is shown. Use that number found there and perform the old calculation to see what it says that the SWR (Standing Wave Ratio) number should be. You may find that it really is pretty good, and certainly close enough for our work.

For us, the main thing is to get the antenna SWR minimum close to the frequency of interest, and adjust the antenna, or the matching network, so that the SWR is down to a number of probably no more than 2 : 1, which also represents just about a 10 % reflected power level back to the source generator. At that point, you are close enough for operational requirements. If the SWR is down to 1.5 : 1, don't worry about trying to get it any lower.

No, the common antenna analyzers we have may not be the equal of laboratory standard quality instruments, but they do have the virtue of great portability and operation away from 117 VAC 60 cps electrical power, in addition to being much smaller and lighter in weight (that portability thing again).

If you truly need even easier portability, look at the iPortable iP30z or the iP60z. This is a very small aluminum cased analyzer that goes into a shirt pocket, and displays the frequency tuned, the SWR, and the impedance, but no sign of the impedance on the display, so you will need to use the old fashioned way of changing the frequency to see if the impedance number rises or falls to see if the reactance is capacitive or inductive. but operationally, the three numbers presented are all that you really need to tune your antenna to where it needs to be. And there are some other similarly sized analyzers that will also work about the same way, such as the Autek RF Analyst, and some others.

And if you forget and leave it at home, you can still do the job with just the built-in SWR indicator in the radio, and do it the old fashioned way. It will take longer, yes, but it can be done.

Enjoy, and 73;

Ralph, N7KGA

Latte Land, Washington

The Norton-Sommerfeld ground is quite good. This is called "real ground"
in the EZNEC codes, I believe.

There are issues with NEC2 with segmentation and the angles at which
wires meet. NEC2 has other issues. The USG is very stingy about NEC4,
which solves some (not all) of these issues, licensing a Fortran code;
I doubt that more than one ham in a hundred can compile Fortran for
Windoze, and then make reasonable use of the result without mouse-clicky
interfaces. Vendors exploit this mercilessly. Academics, for a variety
of reasons, are not so forthcoming as once they were, sending you (from
their tax-funded offices) lawyer-letters instead of source code.

> not, except that you can use them for comparative purposes if you take the

> modeling programs.

W4RNL(SK) has many articles on this subject. www.cebik.com and antennex.com.

But while numeric models have their problems, so do measurements
with the equipment and ad hoc antenna ranges available to hams without
lottery-winning talents. It is probably as dangerous to take an abstract
model and pontificate about its performance in John Doe's backyard,
as it is to make a series of readings in Doe's backyard and talk about
how antenna theory has been overturned. Real measurements get horrible
when we start comparing measurements with a Brand-X meter in Doe's yard
in Chicago with those taken with a Brand-Y meter in Shmoe's seashore DX
Paradise in the lesser Antilles.

Measurements made at the actual site are probably the gold standard,
though.

> Many people model the antenna but forget to include the feedline. You can
> load up a coax feedline with nothing on the end of it.

I deliberately ignore feedlines. Any model I submit here will have a
feedpoint, and any SWR/Z values refer to that point. NEC2 doesn't
do feedlines too well. (Correct me if I'm wrong!)

I need a tutorial on feedline modelling in NEC2 using the TL card, BTW.
URL or Elmering on- or off-list.

We were trying to figure out the placement of the 40 meter trap that came with the antenna since it was not in the manual.

We thought it would be too heavy to have it at the top since it is quite large and the heaviest.

Otherwise we had the traps as per the manual, 10 then 15 and 20 at the top.

> being currently being presented. We'll see . . ..
```

If mmana says 55 ohms ... push the first director a tiny bit towards radiator and you should get closer to 50 ohms

The transformer baluns are used on lower impedance antennas (28 ohms high gain yagi as an example) ... use 2 times 72 ohms (75 ohm) ... that is around 36-38 ohms ... transforming the 28 ohms up to 50 ohms

Yes , strip the ends of each wire and solder them together, one set on each side of center feed point.
If each side is 44 foot long and you use open wire parallel feedline and tuner it will work 80 thru 15.

And I can attest that the individual strands of a 4-wire telephone cable can be used for a dipole. You may be familiar with the Norcal Doublet. I built essentially the same thing from a 50 foot telephone extension cord. Rip out 25 feet of the middle 2 conductors and you have a 25 foot dipole with a 25 foot parallel feed line.

It wasn't great, but it was certainly adequate. At $1.99 (on sale) it was among the cheaper antenna experiments.

Hi all,

Sorry to butt in.

I am hoping to put up a G5RV Jnr in the next few days however one of the supports is a suspect chimney.

As I do not want to destroy the chimney I was wondering if anyone knows what the weight is that is pulled by each leg of a G5RV Junior when it is erected as close as possible to horizontal?

Any ideas or pointers on working it out?

Depends on how tight you pull it. Support the feed point and very little. Pull the ends to make it tight, lifting the feed point, coax and feed line and it can be a lot.

I wouldn't sweat getting it close to horizontal. 20 degree droop is no problem on a dipole. You normally don't pull them tight to allow for sway in the wind, assuming trees and/or towers are used.

What is the other end's support? That's the big worry on the chimney. If it is a tree, you DO NOT want it pulled taught. The tree will sway in the wind and will pull hard on that chimney in a storm. Not good. Plan in designing in a "weak link" in the support on purpose. You want that link to break and not the antenna or structure in a bad storm. Pulley systems and weights are another alternative to allow for movement.

Depends on if your g5rv is made from thicker or thinner wire ... and how much sag you will allow

If pulled hard (to be nearly without sag) the pull force will be nearly in heaven (it is NOT a linear function!)

As more sag you allow and as lihter the wire is as lower the force is

Use al fence wire and the needed force will be WAY lower as when using copper wire

Maybe you can erect a support at the feeding point and have almost no sag then?!?

What about making the feeding point at your chimney and installing a g5rv NOT junior (more bands to play on)

Then your feeding has a support ... and the length that was needed for the jr version should be enough for one leg of the full sized g5rv

(but you have to think where to put the second leg!)

Does not need to be straight (can be a bent dipole)

Sorry, I was on a phone, and do not type well there. If you are trying to pull it horizontal, you will put a lot of pressure on the chimney and the other support. Remember that height of the feedpoint above ground can make a *lot* of difference; I have an antenna like a G5RV, a center fed doublet, which a G5RV is modeled on, and I raised the feedpoint a few feet, and the difference was remarkable, so getting the feedpoint up is important.If you cannot support the center, you will have to pull it horizontal, and pressure on the ends goes up. Weights and pulleys or bungee cord will help when the wind blows, but antenna droop can make the difference between an S-7 and an S-9. I finally put the feedpoint on a rope and hoisted it a few feet up in a tree. Wow!!! Makes a difference on receive too.

Yahoo group: ham-antennas (2014)
Date: 2014-06-13 23:13:05 UTC
From: Andy
Topic: 32796 Message: 32798

The two differences I believe to be true are:

(1) Only the MFJ-269 covers the 440 MHz band.

(2) The MFJ-269 has more resolution on measurements, due to more bits in its A/D converters (something like 12 bits vs. 8 bit converters in the '259 models).

The recently released MFJ-259C is somewhat improved on the '259B ... the new "C" model goes up to 230 MHz but still does not cover the 440 band, and its lower frequency range encompasses the "AM" broadcast band. I don't know if its A/D is different, or what other differences it has vs. the old '259B.

Andy

What you want to know can be found at

http://home.earthlink.net/~w6rmk/math/catenary.htm

The sag of the wire is called the catenary and the link has the formaluias
for figuring the force that will be applied to the end but remember if not
supported in the center use have to add in the weight or pull of the hanging
coax not just the weight of the antenna.

.
Guys,

Any measurement on the laterial strength of the chimney ? No ?
Then you need to use a guy wire on the back-side chimney
so that it will not topple.

Always good to use a support in the middle of the antenna wire,
especially where the Feed-Line & Coax are driving the G5RV.

Equations are great ,
but there will always be unknown variables to spoil the results.

Good mechanical intuition says to support this antenna and the chimney,
at all points.
.
Unless you are Planning a Destructive Test ,
add supports at all points !

Failure of the Chimney is not an allowable option !

Hello Hylton,

I was at a my radio club last night where one of our members gave a talk on Antenna Mast, Antennas etc. He is a structural engineer and one thing he said was if you leave some dip in something like a G5RV Antenna, the less the load will be at the 2 end points where it is attached to either the masts or building such as a chimney. He said that in theory, you will never get a perfectly flat span of wire with a dipole or similar between supports as the end loads when trying to get it perfectly straight would be more than the strength of the wire itself and it would break.

I hope that helps,

Bill - G4ERV

Topic: 32804 Message: 32805

Yes, that will tell you the coax line loss if you use a 50 ohm load at the antenna.
ie., 50 ohm - 50 ohm coax-swr meter -transmitter (Test 1)
50 ohm - swr meter - 50 ohm coax - transmitter (Test 2)
When you connect the antenna it will probably not be 50 ohms and will have reactance.
This will skew the SWR reading at the transmitter. It will also affect the system losses
as the coax is not looking at a resonant, zero reactance 50 ohm load.
I'm not clear just what you are trying to measure. Just the loss in the coax?

Don gave you a good answer about the line loss readings. About a loop antenna, if you are feeding with ladder line one end of the loop to each side of the ladder line. For coax one end of the antenna to the center conductor the other to the shield. If you are feeding with coax you will need a 75 ohm coax transformer or a 2:1 balun for a single band antenna and a 4:1 balun for a multi band loop antenna.

Rich, Kd0zz

Am I reading the diagrams correct, unlike a dipole the right and left lead lines are connected to each other in a loop antenna. thanks Bob

I have several disabilities and some things are difficult. Dumb is not one of them I get to feeling pretty decent today and decided to mow the lawn. The dumb part is I forgot I had not gotten anyone to raise my END fed dipole and it is hidden on the ground in the grass. Long story short I did a great number on the wire, cutting it in two. My question is what might be the best way to repair this Dipole wire and expect it to still function without a lot of difficulty. Any ideas from the group appreciated

Put a Western Union wrap on the two pieces and then sodler them. You might loose a little length so check your match afterwards.

James "Jim" M. Geidl, K6JMG
D.B. Cooper, you have a message.

> I have a mfj swr/power meter. If I set the swr to the lowest at the transmitter and take a power reading and then take the meter to the antenna feed point and take another power reading will this give me a actuate mesure of line loss? Am I reading the diagrams correct, unlike a dipole the right and left lead lines are connected to each other in a loop antenna. thanks Bob

Short answer: yes.
Longer answer: yes.

Chatter:

Assuming the power meter is not erroneous at various SWRs and impedances (and what use would it be if that were so?), then: yes.

The thing to note is that the difference in the two power readings will be different (in general) depending on the various impedances, i.e. depending on the SWR in the line. That's to be expected. If you're after a number to characterize the line, i.e. ohms/meter of attenuation (or some other unit, like dB/m), then use a 50 ohm dummy load instead of an antenna.

Another way to measure the attenuation of a line is to use a calorimeter. (This is explained in one of the ARRL publications.)

What is an end-fed dipole?

I've heard of an end-fed half-wave antenna and other lengths of end-fed wires, but not an end-fed dipole. "Dipole" generally implies it is fed somewhere between the two ends, hence having two 'poles' or lengths being fed.

Regarding splicing, I'll mostly defer to others on that. I imagine the difficulty is longevity under a variety of stresses including tension, flexing, and the elements. I recall having seen arguments to the effect that soldering may not help much, because all the flexing causes it to give way after a while, but in the meantime it might help slow corrosion where the wires need to be in contact. Liquid electrical tape might also help.

Andy

If you don’t have a soldering iron ready or like my antenna a loop that might need a repair a few hundred feet away you can always use a split bolt. The local big box stores like Lowes and Home Depot carry then in several sizes Here is a picture of a assortment from 14 or 12ga to 4/0.

http://i1102.photobucket.com/albums/g453/KD0ZZ/SplitNuts.jpg

I built my coax fed loop with a split bolt in it for adjustment.

What portion got cut? Antenna its self or feedline? It looks like we are in same area by your email address and I may be able to assist you if not to far away.

Maybe a photo of the damage would assist in answering with more detail.

I would twist and solder the wire then cover with heat shrink.
In have had a doublet up with several joints done this way for several years with no issues , and living in Australia as I do , we get some strong winds down here and it with stood them with no problems.
It has now been replaced with a non resonate loop fed with open wire to a 4:1 balun,and I still have 2 joins in this antenna.

Assuming this is stranded wire Jeff's point about the heat shrink is a good one

When splicing stranded wire it has been my experience that because soldered splices are quite rigid and the wire on either side of the joint flexible that the wire fails sooner at the edge of the splice joint much like bending a solid wire back and forth till it breaks. Several layers of heat shrink extending an inch or so either side of the joint would I think "dampen" the flexing moment

Another poster asked what is an end fed dipole? I think what the original poster has would be more properly called and end fed 1/2 wave. Theoretically by the way a 1/2wave dipole and an end fed 1/2 wave, both raised to exactly the same height, have identical radiation patterns and efficiency, ignoring of course feed line losses and matching network losses as the case may be

Joe,

I wholeheartedly agree with the sentiment of you posting. Especially your plea for more civil discourse.

I also think you are far too generous or diplomatic in your secondary consideration of the comment in question. You are probably a far better person than this OM:)

In lifes experience there are those that live by this axiom:
"In order for me to succeed, someone else must fail". Its unfortunate, but true in business and in hobbies. The likelihood is they will never succeed anyway.

The majority of the Ham Radio groups I belong to are not overrun with "snide" remarks, but this was one time ,it certainly was, in my humble opinion. Unfortunate, because Ham Radio is a hobby for helping and "Elmering". The reward of seeing the light bulb go off can make you smile all day.

There is a yahoo group about a chinese HT on yahoo that would curl your toes with the amount of sniping, condescension and rudness.

If you cant say something nice (constructive, instructive, suppportive, kind or necessary) dont say it.

Happy Fathers Day to all the OMs.

Your email reception must be amazing as I have received no comments from Joe. My remark happens to be quite true, not snide. I had a wire that was not yet mounted, I admit to the fact that I forgot about it. My question here was the best way to repair it after I had cut it. I did not ask for the comment concerning how I did any measuring using the wire as it was not in use yet. That was volunteered by someone trying to be superior when in fact it was off topic. When I get the wire repaired and mounted I will indeed run tests and checks to see what if anything has changed from its original design. It is unknown to me why it is necessary for someone to assume I don’t have the mental capacity to do this and make assumptions that are off topic to my question. But if you and Joe feel that you need to discuss it further, then by all means do so. A had at least a couple of understanding souls give me the information I was looking for, and I thank them

I guess the bit dog always barks .....If the criticism was directed at me it hit without much effect. As with most repair suggestions here the suggestions were way over engineered. I have had antennas in use on the ground , I have cut them in half , I have just twisted the wire on a many on the ground and in the air to be more permanently repaired at a later time . Some have been waiting years & operate well without an engineer to sign off on it , any solder , or heat shrink . I am very handicapped .....I went blind back in 88 , God graced me with a second chance . I have one kidney , one lung , a valve from a Bovine in my heart , I have 27 stents , had two back surgeries , and raised five kids working as a used car salesman. I would not hurt a fellers feelings for the world but some questions here have to be made up and some answers are over engineered . If you rendered an apology from this you are welcome and we will all do better.

I guess you could say I am partially disabled, several back surgery's and spinal fusions, makes for bad and week legs. Cant climb myself but I toss a fishing weight over a tree limb, pull a cord back up with a pulley and line on it to provide antenna supports.

Rich, kd0zz

Subject: AW: [ham-antennas] End fed dipole

No need to climb in a tree ... just use a spudgun and some rope

Presumably dates back to telegraph days, and was quite popular back in the (my) day when telephone wires were strung overhead. it is style of wire wrapping primarily for solid wire, questionable for stranded wire (in my experience).

Pictorial here

I agree with all of that.

I have been practicing the habit of ignoring all obnoxious content. I have seen far too many times where a formerly productive thread has been hijacked and transformed into a series of gripes, counter-gripes, and other irrelevant content.

I'd add one category to "If you cant say something nice (constructive, instructive, supportive, kind or necessary) don't say it." - humorous. I can't help it, myself.

I had a report that my signal had a popping in the audio.

You may have some RF in your signal.

I was on HF on USB

I have a remote head set, Mic, PPT hooked up with about 4 ft. of cord.

Please explain what this contact was trying to indicate?

Richard

Before my Ham days, back in the late 70s, I listened to some tapes from a rock music venue right next door to People's Temple in San Francisco. There were many tapes where there was a significant bleed into the audio system of the music venue from the RF generated next door. Jones used Ham frequencies for major communications between SF and Jonestown, Guyana. He had a large number of his congregants get Ham licenses here and in Guyana. There was pretty good proof that the greatest number of the Guyanese Licenses were obtaiend through bribery. And there was a strong suspicion that many of the US Licenses were obtained through bribery or other misconduct by the SF FCC Office.

Ground EVERYTHING before you worry too much about it. Drive a nice 8' copper ground rod outside and run a line into your shack from it and connect every piece of gear to that ground. Also, not a bad idea to tie your house ground to this too.

Now, I realize that any conversation about grounding brings on a religious onslaught of "I know a better way." No doubt that there are a million better ways but sometimes you seek perfection but settle for progress. :-)

As I recall from both my General and Tech license exams, and from the prep therefor,
the National Electrical Code (NEC), which most jurisdictions have adopted, requires
all grounds must be tied to the house ground due, as I recall, the dangers raised by
different potentials at different grounds.

32834. RE: [ham-antennas] Audio and RF

Yahoo group: ham-antennas (2014)
Date: 2014-06-15 23:12:45 UTC
From: KB3YRC
Topic: 32828 Message: 32834

Well Lets start at the Tower it is 33 ft. and is in a yard of concrete. I was instructed to have none of the rebar touch the metal of the tower. I have three ground rods 6 ft. apart and copper from each leg to a ground rod and all three rods bonded together in a ring. I have a ground wire # 4 from the rods to the attic to a mounting plate of Roofing copper where all antennas have a lighting adapter and the rotor wires and protected on this copper. The lines run to a terminal in the basement with a 15” X 15” Copper where all lines go through PL-259 Barrels locked to the copperplate attached to a ground rod just 3 ft. outside the wall. All radios and equipment are bonded to the same ground rod.

I was advised not to tie it to the house ground to keep the lighting out of the house. But as an electrician I like to tie them all together .

Two points of opinion.

This will be open for comment.

Richard

32835. 80 meter antenna

Yahoo group: ham-antennas (2014)
Date: 2014-06-16 01:14:59 UTC
From: dalecole3502@...
Topic: 32835 Message: 32835

There was a posting about Cat 5 cable (on this board?) being used as a antenna (dipole). As a 75 watt, rock-bound, novice, I used TV twin lead connected to some 75 or 50 coax to the shack. If I was to take all of the ends (of the Cat 5) and and twist together, and run to a center conductor i.e. coax, could I run that into the shack and run 100 watts +/- to my TS 570 (and possibly a tuner), and be somewhat effective on 80/75 meters?

twin lead has a lot of good antenna applications like the roll up J-Pole--
but Im told, and I do not why, to not use the foam insulated stuff

32837. RE: [ham-antennas] 80 meter antenna

Yahoo group: ham-antennas (2014)
Date: 2014-06-16 01:35:48 UTC
From: John Murphy
Topic: 32835 Message: 32837

Absolutely!!! At those power levels any type of wire will work. Of course I must say it, you need to not only make sure the center conductor is connected, but the shield is connected to the other side of the dipole. This is said due to the way the question was asked. I am not thinking that you (or anyone else on this list) is a dummy and do not know this simple information, however the way the question was worded, leads me to think that you are not going to make a full dipole, and only have one wire connected to your coax lead in.

There was a posting about Cat 5 cable (on this board?) being used as a antenna (dipole). As a 75 watt, rock-bound, novice, I used TV twin lead connected to some 75 or 50 coax to the shack. If I was to take all of the ends (of the Cat 5) and and twist together, and run to a center conductor i.e. coax, could I run that into the shack and run 100 watts +/- to my TS 570 (and possibly a tuner), and be somewhat effective on 80/75 meters?

Thanks John;
You are so correct, that one side will be "hot" and the other side "cold". One leg would serve as the radiator and the other as the sheild. A true di-pole, with a center conducter, fed by a coax line.

Absolutely!!! At those power levels any type of wire will work. Of course I must say it, you need to not only make sure the center conductor is connected, but the shield is connected to the other side of the dipole. This is said due to the way the question was asked. I am not thinking that you (or anyone else on this list) is a dummy and do not know this simple information, however the way the question was worded, leads me to think that you are not going to make a full dipole, and only have one wire connected to your coax lead in.

Split bolts are normality made of different grades of silicon bronze and will hold up outside in the mid-west with no problem.

Different grades so the nut does not gall on the bolt. I have never seen a brass one. Normal brass would be too soft.

That type of splice can be done on stranded wire very easily. Just make sure you tin the wires beforehand (should do that anyway with any wire splices that will be soldered).

I would suggest using some marine grade heat shrink on the splice after soldering it - just make sure you put the tube on BEFORE you make the splice and solder it... Been there a few times.

So, just to be sure I read it correctly....

You have a #4 Cu EGC running from your tower ground rods at ground level up to Cu plate at attic level? Then the lines (both coax and rotator control) that pass through that plate drop back down to basement level and attach to another Cu plate that is attached to yet another ground rod?

I was advised not to tie it to the house ground to keep the lighting out of the house. But as an electrician I like to tie them all together .

Two points of opinion.

This will be open for comment.

Richard

Ground EVERYTHING before you worry too much about it. Drive a nice 8' copper ground rod outside and run a line into your shack from it and connect every piece of gear to that ground. Also, not a bad idea to tie your house ground to this too.

Now, I realize that any conversation about grounding brings on a religious onslaught of "I know a better way." No doubt that there are a million better ways but sometimes you seek perfection but settle for progress. :-)

James "Jim" M. Geidl, K6JMG

What is EGC Electrical Ground Conductor ?

At the tower 16 Feet total in the ground grid ring

From there to the attic 15-18 Feet

At the shack from 5-6 feet at the most to the Rod

4 or # 2 Solid Copper

3.990 I was on my Head set and changed to the hand mic but was told if it changed.

Well Lets start at the Tower it is 33 ft. and is in a yard of concrete. I was instructed to have none of the rebar touch the metal of the tower. I have three ground rods 6 ft. apart and copper from each leg to a ground rod and all three rods bonded together in a ring. I have a ground wire # 4 from the rods to the attic to a mounting plate of Roofing copper

where all antennas have a lighting adapter and the rotor wires and protected on this copper. The lines run to a terminal in the basement with a 15” X 15” Copper where all lines go through PL-259 Barrels locked to the copperplate attached to a ground rod just 3 ft. outside the wall. All radios and equipment are bonded to the same ground rod.

I was advised not to tie it to the house ground to keep the lighting out of the house. But as an electrician I like to tie them all together .

Two points of opinion.

This will be open for comment.

Richard

Ground EVERYTHING before you worry too much about it. Drive a nice 8' copper ground rod outside and run a line into your shack from it and connect every piece of gear to that ground. Also, not a bad idea to tie your house ground to this too.

Now, I realize that any conversation about grounding brings on a religious onslaught of "I know a better way." No doubt that there are a million better ways but sometimes you seek perfection but settle for progress. :-)

James "Jim" M. Geidl, K6JMG
D.B. Cooper, you have a message.

Been there, didn't do it. Learned by not doing, alas.

While on the subject of heat-shrink, a few questions:

(1) I need to clarify whether the following is something people do, and that I've heard of, or if it is the product of a bout of brain fever: Over the joint, spread a generous layer of RTV sealant, then, before the sealant hardens, slip the heat-shrink over it. Then heat, and later clean up the sealant that has squeezed out. I've yet to try this, but it /sounds/ OK. Is it?

(2) I've definitely read that heat-shrink which has an adhesive on its inner wall is superior. and that one can add adhesive to heat-shrink that lacks it. If so, what kind of glue is nice? Same as (1)? or is there something preferred?

(3) Instead of sealant or adhesive, how does heat-shrink behave over one of the various "magic goos" that don't harden or vulcanize themselves or act as adhesives? There's some stuff used on aluminum to prevent oxidation, for example, and other stuffs that claim to prevent bimetallic corrosion, and other things. What of them? What of heat-shrink over self-amalgamating rubber tape?

(4) What are the failures of heat-shrink?

(5) Is there a "heat-shrink tape", i.e. something like self-amalgamating tape, that can be applied, allowed to "self-amalgamate" then be heat-shrunk?

In the application discussed in the original thread heat shrink like
most plastic derivative products is subject to
eventual degradation due to UV radiation (sunlight) , and eventually (
years and years) cracks and gets brittle. My personal experience in
using this for sealing PL-259 connectors is 5+ years. There is more than
one formulation of heat shrink some are more "plastic feeling" others
more "rubber" like than others , color will also affect the amount of UV
absorbed.

I use a 5/16 bolt split down the middle and you just run the wires thru it and clamp down. It is weather proof, does not rust. The whole thing is about the size of a dime. The one in the picture is for 12 to 10ga but smaller wire 14/16 can be used and the do make the bolts in a smaller size also. It is a light weight solution to a movable / adjustable wire splice.

EGC = Equipment Grounding Conductor

That's about 36-40 feet of grounding wire plus the length of cable for your hand mike and/or headset. All of that is approaching 1/4 wave on 75m (I know it's a bit short of that). If there is any way for you to shorten your grounding runs, that might improve things. Remember, you want as low of an impedance to ground as you can get. The longer the runs, the higher the impedance AND the longer the run the more likely the ground system will become part of, or at least interact with, the antenna system which will put RF onto it and you don't want that coming back into your shack.

You shouldn't be using standard RTV/Silicone sealant on coax or coax
connector. They use Acetic acid for the curing process and emit ammonia
during the curing process which can contaminate and degrade the coax and/or
metals of the connector.

Good but not the best

> (2) I've definitely read that heat-shrink which has an adhesive on its
> inner wall is superior. and that one can add adhesive to heat-shrink
> that lacks it. If so, what kind of glue is nice? Same as (1)? or is
> there something preferred?

If i wanna seal something with a heat shrink tubing and have only tube
without glue in it then I seal my connection with hot melt glue ... and
while still hot add the tubing over it

Heat from the glue then shrinks the tube somewhat... adding more heat with
hot air gun and some glue squeezes out ... let cool down ... done

>
> (3) Instead of sealant or adhesive, how does heat-shrink behave over
> one of the various "magic goos" that don't harden or vulcanize themselves
> or act as adhesives? There's some stuff used on aluminum to prevent
> oxidation, for example, and other stuffs that claim to prevent bimetallic
> corrosion, and other things. What of them? What of heat-shrink over

Nothing known here about any magic goo ... but ... I had a pl connection
outside that was ONLY sealed with self amalgating tape (scotch 3m tape)

Nothing else! ... after cutting away the tape the connectors inside looked
like brand-new ... was outside for over 20 years!!! In sun, rain and snow
```

So you see that tape is very good

Not needed to add heat to the tape after putting it on the connection

You can add a protection layer of a good pvc tape above the self amalgating tape just to protect it from unwrapping till the tape is set (amalgated)

But when applied right that is NOT needed

> self-amalgamating rubber tape?
>
> (4) What are the failures of heat-shrink?

Heat shrink tubing??? Does survive almost anything especially the version with the glue inside and a bit thicker wall

These tubings come in different sizes and QUALITY so look before buying
>
> (5) Is there a "heat-shrink tape", i.e. something like self-amalgamating
> tape, that can be applied, allowed to "self-amalgamate" then be
> heat-shrunk?
>

Already answered ... heating is not needed on these self amalgating tapes

Adding some SLIGHT heating can help for a better seal (but only a tiny bit of heat!!)

At the tower from each leg to a rod is Three feet and the ring around to each rod Buried is 6-9 Feet.

At the shack on the other end of the house 3 feet from the rod to my connector plate of coaxes.

The tower is a 33FT crank up , with a 5 Ft Mast. The cables come down the tower to about 9 FT off the ground and go in the side of the house in the attic to a ground block of Copper.

The longest piece from the grounding plate and 3 feet across the attic and (needs routed and mounted) down the side of the house to the grounding ring.

All radios and equipment are bonded in the shack to copper wire going outside.

See my pictures on QRZ

What is your take on hooking the grid to the water pipe?

Richard

EGC = Equipment Grounding Conductor

That's about 36-40 feet of grounding wire plus the length of cable for your hand mike and/or headset. All of that is approaching 1/4 wave on 75m (I know it's a bit short of that). If there is any way for you to shorten your grounding runs, that might improve things. Remember, you want as low of an impedance to ground as you can get. The longer the runs, the higher the impedance AND the longer the run the more likely the ground system will become part of, or at least interact with, the antenna system which will put RF onto it and you don't want that coming back into your shack.

So, just to be sure I read it correctly....

You have a #4 Cu EGC running from your tower ground rods at ground level up to Cu plate at attic level? Then the lines (both coax and rotator control) that pass through that plate drop back down to basement level and attach to another Cu plate that is attached to yet another ground rod?

<ham-antennas@yahoogroups.com> wrote:

Well Lets start at the Tower it is 33 ft. and is in a yard of concrete. I was instructed to have none of the rebar touch the metal of the tower. I have three ground rods 6 ft. apart and copper from each leg to a ground rod and all three rods bonded together in a ring. I have a ground wire # 4 from the rods to the attic to a mounting plate of Roofing copper where all antennas have a lighting adapter and the rotor wires and protected on this copper. The lines run to a terminal in the basement with a 15” X 15” Copper where all lines go through PL-259 Barrels locked to the copperplate attached to a ground rod just 3 ft. outside the wall. All radios and equipment are bonded to the same ground rod.

I was advised not to tie it to the house ground to keep the lighting out of the house. But as an electrician I like to tie them all together .

Two points of opinion.

This will be open for comment.

Richard

Ground EVERYTHING before you worry too much about it. Drive a nice 8' copper ground rod outside and run a line into your shack from it and connect every piece of gear to that ground. Also, not a bad idea to tie your house ground to this too.

Now, I realize that any conversation about grounding brings on a religious onslaught of "I know a better way." No doubt that there are a million better ways but sometimes you seek perfection but settle for progress. :-)

As Geoff says RTV can be a problem. When you buy the RTV be sure it is type II or marked non-corrosive

Rich, Kd0zz

>and later clean up the sealant that has squeezed out. I've yet to try
>this, but it /sounds/ OK. Is it?

You shouldn't be using standard RTV/Silicone sealant on coax or coax connector. They use Acetic acid for the curing process and emit ammonia during the curing process which can contaminate and degrade the coax and/or metals of the connector.

I agree Tony, it would be easy to replace, but I think he asked about a repair. Not everybody keeps couple thousand ft of silver plated wire around for antenna repair, HiHi.

/quote There's some stuff used on aluminum to prevent
oxidation, for example, and other stuffs that claim to prevent bimetallic
corrosion, and other things. What of them? What of heat-shrink over
self-amalgamating rubber tape? quote/

This "No Aluminum Oxide" grease is NOT an adhesive.
However,
"NoAlox" and "PenTrox" are very good at protecting prepared Aluminum surfaces
from the quick oxidation that occurs between Aluminum and Oxygen.

google for MikeHolt electrical website, in the forums section for discussions about
aluminum wiring
in which I have parcipated.
google for NY-Inspect for a website with a 100 page section devoted to aluminum wiring
methods and problems and solutions.

Or, just don't try using this Oxide-Inhibiting-Grease as an adhesive.

32867. My Antenna Mystery Solved - See if you could have figured this one out...

Yahoo group: ham-antennas (2014)
Date: 2014-06-17 12:15:13 UTC
From: myfamilydotcom@...
Topic: 32867 Message: 32867

Setting: 32' self-support tower wih Mosely 5-band HF beam, Cushcraft VHF beam and Aliance HD-73-1 rotor mounted inside tower in a typical rotor-mount shelf and tower-top thrust bearing configuration.

Clue #1 - This spring when doing post-winter site checks, I discovered 2 3/8" stainless steel bolts sitting neatly at dead centre on the concrete tower pad. They still had lock-washers on their collars, so I wondered what the heck that was all about. Eventually I figured that I must have been working on a project and put them there for safe-keeping - but oddly I could not recall that. Things worked fine...

Clue #2: - About a month later I turned on my Aliance rotor control box late one evening to scan around. Oddly, the control box dial showed the antenna was parked at due south - something I would not likely do.

Clue #3: - When I attempted to activate the rotor, I immediately blew a control box fuse. Not good.

Clue #4: - I replaced the fuse, hoping perhaps the beam had blown to south position and was mechanically jammed. I hoped I could unstick it. I turned on the tower-cam and observed that while blowing the fuse AGAIN, the beam did not even budge. Now really not good.

Clue #5: - When trying a 3rd fuse (I know, not a great idea...) I observed the Azimuth meter needle moving somewhat erraticlly, and trying to go slightly off scale. The ohmmeter readings from inside showed abnormal readings on several leads. OK - shut off power and visit site in morning.

Clue #6: - Site at first looked normal - rotor cables seemed tight and no signs of tampering at the splice enclosure and along the tower.

Clue #7: - While wandering around the base of the tower like an inspector, I noticed nothing unusual until from one direction, the mast looked like it was lop-sided (not quite vertical). Then I figured it out:..

Can you figure out what had happened?

.
.
.

Answer: - The neat placement of the bolts with their lock-washer was a misleading clue. First off, I could not remember these bolt types in use at the tower or antenna structure. If they fell 32'. they'd have bounced off the concrete pad and been in the next county, but no they were neatly in a little pile.

These bolts turned out to be 2 of the rotor mount bolts (the ones bolting through the rotor support shelf up inside the rotor bell housing to keep the whole totor in place.

I believe that 2 had worked their way loose over the winter, and fell, but landed in deep snow at the tower base. After weeks/months of warming weather they slowly descended one-by-one to the tower base, lock washers and all. The second bolt must have done the same.

Some time later (the night I decided to give the bands a try) the 3rd bolt must have dropped out similarly. Now it bounced off the concrete base and was eventually spotted 6 feet away, lockwasher long gone.

When I rotated the rotor, the antenna stayed in place, and the rotor unit rotated about the last (4th) remaining screw, until the electrical cable was strained and pulled some conductors off the rotor, shorted out some wires and blew fuses until I figured out what was happening.

The wires evidently reverse-fed motor power leads back through the meter sense leads to the control box, resulting in erratic meter operation and blowing a few small silicon diodes on the control box (designed to protect the meter - thanks!).

With bolts back in place with lock-washers, 2 new diodes, and a morning up the tower re-connecting the strained cable assembly - all is well.

Lesson learned - make sure that these 4 stainless steel bolts are tight - I would not have thought that I could have mistanely left them finger-tight, but that is a possibility - or maybe they worked themselves loose over time since they are stainless steel, and the rotor housing is cast aluminium, and the temperature coefficients and stuff might favour evential loosening - I don't know - but I can tightenen them or check them from time to time and keep this from happening again.

MAybe you guys would have figured this out faster?

I am a little old and slow and don't ways understand all need to cover a solder joint outdoors with all this stuff. I have always used regular lead solder indoors , a 60/40 or 63/37 mix. For outdoor antenna work be it copper tubing on a J-Pole , slim jim or 14 or 12ga copper wire loop I use Stay-Brite. Stay-Brite is a lead free , silver bearing solder. Note, I said silver bearing , not silver solder so it does not require a torch for wire work. It will not turn dark grey and fuzz up like some lead solders and requires no covering from the elements. There are several lead free, silver bearing solders on the market, I just happen to use the Stay-Brite brand. Home Depot carries it as do all hardware and plumbing stores.

Rich

You are correct for electrical integrity there is no need for shrink wrap in the case of wire splicing

Shrink wrap however does add some degree of increased mechanical integrity when splicing stranded wire in an antenna system. My personal experience is that a spliced stranded wire tends to fail again at the point where the flexible wire ends in the rigid solder joint. The heat shrink tends to dampen the amount of flexing at the joint and thus prolongs the the point of failure due to bending fatigue

YMMV

Another point with the silver bearing solders.

Years back, when that stuff was just coming out and I was working for a company who had enough industry presence that I could ask for samples, well, the paper specs that came in the box said that the non-lead soldered joints were about three times as strong as those made with the 50-50 plumber's solder it was replacing. 50-50 is even a bit stronger than 60-40, or 63-37 radio solder.

In 1994 I put together a double extended zep "J"pole made out of 1/2" copper. Stands ten or so feet tall, with multiple joints, mounted only at the base. With all the storms and wind, none of those joints have come loose. Takes a bit more heat to work, but definitely Good Stuff!

I would not have put the bolts in from the bottom in the first place!
When they get lose they fall out as you found out.

Put them in from the top using longer ones if need be (Welded nut on top)
then put lock washers and nuts *and Locktite* on threads and secure them.

If nut loosens and falls off the bolt is still holding plate in place!

This is somewhat impossible when he was screwing into a housing .
Locktitie is also not a good option on something that may be disabled
in the air . In 35 years I have never had such a failure . i think he
found his problem when he opened the possibility on never tightening
them when assembling years ago . Wq5B

In the professional tower world the bolts are put in from the bottom. Upon inspection a bolt is easier to see than a nut. If a nut falls off and becomes lost the tower is just as unsecure. The bolt alerts to the problem and the hole can usually be spotted from the ground using a telescope. Not lying!

I would not have put the bolts in from the bottom in the first place!
When they get lose they fall out as you found out.

Put them in from the top using longer ones if need be (Welded nut on top) then put lock washers and nuts and Locktite on threads and secure them.

If nut loosens and falls off the bolt is still holding plate in place!

Yep. My 180 foot Rohn 65 tower has all of the bolts going up. While I don't climb the tower any more, it was a yearly maintenance trip to the top to visually check ALL of the nuts and safety lock wires to be in the proper location and snug. My tower has no loose nuts, pardon the pun.

Professional towers are always installed with the bolts pointing UP
so when the nut falls off you can see sky up the through the hole, a
safety feature.

Well if it isn't the "L" in KLM...or is it the "K"? I can't remember the story Mike told me once. Its an honor to meet you! If you ever need help with your tower, let me know! I'll climb a 180'er!

Subject: Re: [ham-antennas] My Antenna Mystery Solved - See if you
could have figured this one out...

This is somewhat impossible when he was screwing into a housing .
Locktitie is also not a good option on something that may be
disabled in the air . In 35 years I have never had such a failure
. i think he found his problem when he opened the possibility on
never tightening them when assembling years ago . Wq5B

[ham-antennas] wrote:

I would not have put the bolts in from the bottom in the first
place!

When they get lose they fall out as you found out.

Put them in from the top using longer ones if need be (Welded nut
on top) then put lock washers and nuts and Locktite on threads and
secure them.

If nut loosens and falls off the bolt is still holding plate in
place!

[ham-antennas] <ham-antennas@yahoogroups.com> wrote:

Setting: 32' self-support tower wih Mosely 5-band HF beam,
Cushcraft VHF beam and Aliance HD-73-1 rotor mounted inside tower

in a typical rotor-mount shelf and tower-top thrust bearing configuration.

Clue #1 - This spring when doing post-winter site checks, I discovered 2 3/8" stainless steel bolts sitting neatly at dead centre on the concrete tower pad. They still had lock-washers on their collars, so I wondered what the heck that was all about. Eventually I figured that I must have been working on a project and put them there for safe-keeping - but oddly I could not recall that. Things worked fine...

Clue #2: - About a month later I turned on my Aliance rotor control box late one evening to scan around. Oddly, the control box dial showed the antenna was parked at due south - something I would not likely do.

Clue #3: - When I attempted to activate the rotor, I immediately blew a control box fuse. Not good.

Clue #4: - I replaced the fuse, hoping perhaps the beam had blown to south position and was mechanically jammed. I hoped I could unstick it. I turned on the tower-cam and observed that while blowing the fuse AGAIN, the beam did not even budge. Now really not good.

Clue #5: - When trying a 3rd fuse (I know, not a great idea...) I observed the Azimuth meter needle moving somewhat erraticlly, and trying to go slightly off scale. The ohmmeter readings from inside showed abnormal readings on several leads. OK - shut off power and visit site in morning.

Clue #6: - Site at first looked normal - rotor cables seemed tight and no signs of tampering at the splice enclosure and along the tower.

Clue #7: - While wandering around the base of the tower like an inspector, I noticed nothing unusual until from one direction, the mast looked like it was lop-sided (not quite vertical). Then I figured it out:..

Can you figure out what had happened?

.

.

.

Answer: - The neat placement of the bolts with their lock-washer was a misleading clue. First off, I could not remember these bolt types in use at the tower or antenna structure. If they fell 32'. they'd have bounced off the concrete pad and been in the next county, but no they were neatly in a little pile.

These bolts turned out to be 2 of the rotor mount bolts (the ones bolting through the rotor support shelf up inside the rotor bell housing to keep the whole totor in place.

I believe that 2 had worked their way loose over the winter, and fell, but landed in deep snow at the tower base. After weeks/months of warming weather they slowly descended one-by-one to the tower base, lock washers and all. The second bolt must have done the same.

Some time later (the night I decided to give the bands a try) the 3rd bolt must have dropped out similarly. Now it bounced off the concrete base and was eventually spotted 6 feet away, lockwasher long gone.

When I rotated the rotor, the antenna stayed in place, and the rotor unit rotated about the last (4th) remaining screw, until the electrical cable was strained and pulled some conductors off the rotor, shorted out some wires and blew fuses until I figured out what was happening.

The wires evidently reverse-fed motor power leads back through the meter sense leads to the control box, resulting in erratic meter operation and blowing a few small silicon diodes on the control box (designed to protect the meter - thanks!).

With bolts back in place with lock-washers, 2 new diodes, and a morning up the tower re-connecting the strained cable assembly - all is well.

Lesson learned - make sure that these 4 stainless steel bolts are tight - I would not have thought that I could have mistanely left them finger-tight, but that is a possibility - or maybe they worked themselves loose over time since they are stainless steel, and the rotor housing is cast aluminium, and the temperature coefficients and stuff might favour evential loosening - I don't know - but I can tightenen them or check them from time to time and keep this from happening again.

MAybe you guys would have figured this out faster?

Quad antennas by virtue of the fact you are working with full wave length elements , rather than shorter and electrically loaded elements should give greater sensitivity and transmission signal
I would stay with the Quads unless there were factors that prevent this
I do not have space for either , and now use a non resonate loop , which appears to perform reasonably well certainly better than the dipole which it replaced

Tom,

I've contemplated that myself. The problem is you'll need two yagis because ALL or at least most 5 band yagis have severe deficiencies on warc bands and usually sub par 10,15,20 performance to accommodate warc bands.

for 20-6, you might look at homebrew hex beam construction. Gives about the performance of a 2 element yagi, is around 10' radius... small wind load, and fairly easy construction.

I'm putting one up at Field Day for the south wake ARC here. small TV type rotor to aim the thing... --I'm going with the wide band version, which has slightly lower gain than the narrow band.

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

I certainly enjoy the group, and occasionally feel motivated to throw in a comment.
This is one of those times.

I have been an amateur for many years, and have, by way of my job as a forest fire air tanker pilot (retired), been shuffled from one remote airport to the next.

I always carried my FT102 in the back of the aircraft, and when dispatched to some remote airstrip, I made sure I had my slingshot, open faced spinning reel, support rope and at least an 80 mtr doublet (dipole fed with laddderline) 4 to 1 current balun, and a cheapo manual tuner, along as well.

Arrive at the airstrip, secure the aircraft, and after being stood down, I could have an antenna up in any two of the many trees,and be working good dx within a half hour. The doublet is a simple, elegant, efficient all band antenna, that will not destroy the pocket book, and will get you on the air. I realize many of you, do NOT have big trees, but often a simple pair of poles will help you get a wire antenna in the air.

My point is, that often times, simple, and inexpensive will work just as well as expensive and complex....and goodness knows, there are many manufacturers out there, only too willing to help you spend your money on something, that may or may not work. There is NO perfect antenna, and my experience, and my budget, has shown me that simple is the best for me.

Maybe it will work for you too!

Good Dx
and 73

No perfect antenna, but there is a best all around antenna and you have described it. You CAN DX on a doublet, you do not need a multi-thousand dollar rig, a tower and a beam (though they all help), but the best antenna you can afford. A dipole cut for 20 meters and fed with balanced line is hard to beat. For 40 and 80, a 120 foot wire to a nearby tree and directly into the matcher.

I agree whole heartedly Alex. When you have kids vacuuming out the wallet, the budget is pretty tight for ham radio. Although I use a large loop now, I originally started 35 yrs ago, with an 80 mtr doublet, balanced feeder. It worked great, and was excellent DX on the higher bands, where I had multi wavelengths on the wire...

Best part, is the cost!! Inexpensive.

Yep, and here at the shack, I am radio poor (spent too darn much on them, but I LIKE them), and I have an 80 meter doublet and a 20 meter doublet, one north south, and the other east west. Works great, and in the year since I became active (last May), I have logged 65 countries, and that is probably averaging about 30 minutes a day - some days I don't even turn a rig on except for VHF/UHF. If I were like some, on it all the time, I would have collected a DXCC already.

I like the KISS approach. Here is a simple multiband idea I used last week on a fishing trip. If you take a horizontal 1/2 wave OCF 68 foot piece of wire 10 to 15 feet AGL, you get 40,20,15, and 10 all < 3:1. Yes, you need a ATU. So what? Then if you short out the feed point and end feed it against ground you have a 1/4 wave NVIS antenna for 80. Neat simple portable antenna.....

Topic: 32900 Message: 32900

I am about to take a job in the Bay Area near San Jose and will likely be renting for awhile. I will be selling the house in San Diego and my towers and great antenna farm is coming down soon. I wanted to get some recommendations for magnetic loop antennas as they might be my only option for condo living. I have been looking at the MFJ antennas and wonder if anyone has an opinion of them. Also the Alex loop looks interesting but power is limited to 20W. Are there any other commercial manufacturers out there.

Thanks for the recommendations in advance.

I think I would look else where for an antenna. In 35 years a DXing I do not believe I have run across a competing station from six land running less than 2000 watts . I was told it was something about the Green law in Cal. Good luck and good DX on your move . Chuck Wq5B

I don’t know that much about using ladder line or building a doublet, but would it be possible to connect a short piece of coax to your tuner. I don’t have a tuner that will do ladder line and my budget will be tight for a few years

I agree whole heartedly Alex. When you have kids vacuuming out the wallet, the budget is pretty tight for ham radio. Although I use a large loop now, I originally started 35 yrs ago, with an 80 mtr doublet, balanced feeder. It worked great, and was excellent DX on the higher bands, where I had multi wavelengths on the wire...

Best part, is the cost!! Inexpensive.

73 Good DX John

Add a 1:4 balun to your tuner and it will do ladderline

If you canb not find a match on a higher band or if it is a bit tricky to tune just add (or shorten) a few feet of ladderline and then try again

Nearly all manufacturers of tuners build their tuners that way (adding a balun to one of the outputs for ladderline) ,,, so why not do that on your tuner?!?

You also can add the tuner outside with a few feet of coax between that balun and your tuner in the shack (sometimes called "remote balun")

On some rigs with a good built-in tuner you also can stick that balun at the rig (and use the internal tuner with that balun to tune ladderlimne fed antenna)

With a bit of "calculating over the thumb" you can easy see what antenna length and what ladderline length gives a higher or lower impedance at the shack end

So ... there is no "magic" behind using ladderline

32905. Vertical antenna modeled

Yahoo group: ham-antennas (2014)
Date: 2014-06-20 19:26:34 UTC
From: schwartzj22@...
Topic: 32905 Message: 32905

To all,

I have been doing some modeling and just thought I would pass along this info.
I modeled a vertical antenna for 10 – 20M. For a 3.6 meter long vertical wire with the base 10 feet off the ground and used the following 4 counterpoise wire lengths in meters:
7.03 (20M and 10M)
4.53 (17M)
3.41 (15M)
2.35 (12M)

The ends of the CPs are about 6.5 feet off the ground and at the antenna base of course they are 10 feet off the ground.

Here are the SWRs:

2.15 20M
1.1 17M
1.09 15M
1.08 12M
2.22 10M

These SWRs are for 50 ohms so I could just use 50 ohm coax. Might be a good idea to add a 1:1 balun at the antenna.

Of course someone could do the modeling for 10-40M but since my telescopic pole is 32 feet I did it for 10-20M. I already use the pole for one end of a dipole. Might as well try this idea to add a vertical.

Cost without the pole is about $12 for 100 foot of wire (but you only need about 69 feet).

Thoughts? Seems too good to be true.

Tks,

Joel – N3GSE

Did you model it with the dipole above so rou can get an idea about interaction and pattern distorsion?

Good idea for adding multiband performance to your pole.
Ant just a little short for 20 but at 2 : 1 SWR should work well with about
90 % efficiency.
With small tuner radio will be happy.
I have used vert with multilple 1/4 wave vertical wires on 20 to 10 with
good performance.

32911. Modelling design descriptions

Yahoo group: ham-antennas (2014)
Date: 2014-06-20 20:44:20 UTC
From: farrerfolks@...
Topic: 32911 Message: 32911

Hi All,

I would like to suggest we include more information when telling us of a new design.

It will allow others to duplicate the design more easily.

Here goes:
1. Always indicate the ground type used. Many designs don't work the same in the wrong ground type.
2. Let us know the AGL of the antenna elements.
3. Antenna wire size.
4. Wire material and loss used.
5. If possible include the SWR plot, not just single frequency.
6. Include the antenna view if possible. A picture speaks a thousand words hi.
7. Include the type and version of the software used.
8. Last, it is great if you go to the output toolbar and select the description and copy it into the text.

I think that if these are provided, us modelling geeks can duplicate your work.....

Cheers,

Mel, K6KBE

32917. Re: Vertical antenna modeled

Yahoo group: ham-antennas (2014)
Date: 2014-06-20 22:05:23 UTC
From: schwartzj22@...
Topic: 32905 Message: 32917

Hi Don,

The vertical length was specifically chosen so that I could have low enough SWR on all 5 bands but with just one vertical wire and small tuner. The CPs were also specifically chosen so I could minimize their number.

If I had a longer vertical wire (for 20M) then 10M would suffer no matter what length of CP I used.

If it works it will be a neat setup. The model looks good!

Tks,
Joel - N3GSE

Yes, check out Balun Designs. Google it.

Add a 1:4 balun to your tuner and it will do ladderline

If you canb not find a match on a higher band or if it is a bit tricky to tune just add (or shorten) a few feet of ladderline and then try again

Nearly all manufacturers of tuners build their tuners that way (adding a balun to one of the outputs for ladderline) ,,, so why not do that on your tuner?!?

You also can add the tuner outside with a few feet of coax between that balun and your tuner in the shack (sometimes called "remote balun")

On some rigs with a good built-in tuner you also can stick that balun at the rig (and use the internal tuner with that balun to tune ladderlimne fed antenna)

With a bit of "calculating over the thumb" you can easy see what antenna length and what ladderline length gives a higher or lower impedance at the shack end

So ... there is no "magic" behind using ladderline

My two centavos worth:

I have an 88 foot long doublet that is pretty much flat except for the last five feet on one end - it droops down a little. Center is about 45 feet up, attached to the top of an old fiberglass windsurfing mast strapped to a second floor chimney. The wire is from The Wireman and is number 26 Silky Coat. running from the doublet center to the other end of the house is about 110 feet of 450 ohm ladder line. I suspended it on fiberglass poles about 10 feet above ground and about eight inches from the side of the building. At the shack end I have that ladder line connected to a 4:1 balun from Balun Designs. I installed it under the eves so there is little chance of water intrusion to it OR the coax. From the balun, I run about ten feet of RG8-x coax to the back of my Elecraft KAT500 auto tuner.

The KAT500 has no problem finding a match to this antenna on 40-6 meters. It struggles a little on 80 but eventually gets it down to about 1.6:1. Same thing for the internal tuner on my K3 and the internal tuner on my KX3. Performance-wise, this is one of the best antennas I've had in 50 years of hamming. Is it the equal of a six element yagi at 100 feet on 20-10 meters? Not a chance. But it works and I have no problem working just about any station I can hear. Using this doublet I was able to achieve Five Band Worked All States (5BWAS) starting at zero in just over three years, and that was with two young kids at home and not a ton of time devoted to the radio. Also have worked a lot of DX stations with it.

I'd heartily recommend a ladder line fed doublet any day. Use a 4:1 balun, a short length (the shorter the better) of coax to your antenna tuner and you are in business.

Well post results when you build it. It looks like a good balcony antenna
for some folks and a simple portable antenna.
Especiaally in the US there are many stations to talk with. Most of my
contacts are 3000 miles or more away. All contacts are DX, Hi.

> 7.03 (20M and 10M)
> 4.53 (17M)
> 3.41 (15M)
> 2.35 (12M)

I assume these are arranged so that from above they are in a cross shape.
if the 7.03m cp is N, then I put 4.53m W, 3.41m S and 2.35m E.

I modelled this as aluminum wire, 1.63 mm diameter. (My little program is hardwired for Al for verticals, but the difference will not matter much.)
I used a Norton-Sommerfeld ground.

> The ends of the CPs are about 6.5 feet off the ground and at the antenna base of course they are 10 feet off the ground.

> These SWRs are for 50 ohms so I could just use 50 ohm coax. Might be a good idea to add a 1:1 balun at the antenna.
>
>
> Of course someone could do the modeling for 10-40M but since my telescopic pole is 32 feet I did it for 10-20M. I already use the pole for one end of a dipole. Might as well try this idea to add a vertical.

I didn't include a nearby dipole. Such a dipole will probably interact with any counterpoises that lie in same vertical plane as the dipole, i.e. are "pointing the same way (or the opposite way)". The feedline to the dipole is another interaction candidate. I would suggest grounding the feedline and shorting the two parts of the feedline on the dipole when modelling the vertical. (And when using it, too).

>
> Cost without the pole is about $12 for 100 foot of wire (but you only need about 69 feet).
>
> Thoughts? Seems too good to be true.

I agree, seems too good. I could not duplicate your reported SWRs, except for the result in/near the 15m band at 20.962MHz, VSWR=1.02. The antenna at this frequency had significant currents only in the vertical element and in the S (3.41m) counterpoise. The radiation pattern was directional (gain 1.5dbi, F/B 2.4 db). Direction of max gain about 130 degrees, i.e. SW. On other bands, VSWR is higher.

20m - ~67
17m - ~6.5
15m - ~2
12m - ~12
10m - ~10

These counterpoises are asymmetric, and things look more like models of bent and somewhat verticalized off-center fed dipoles.

I respectfully suggest you may have erred in specifying the antenna to your simulation s'ware. Possibly you entered the height as 10 meters, and the ends of the CPs at 6.7m?

I may have misunderstood how the counterpoises are arrayed.

My NEC2 compatible input deck on request. EZNEC might be able to read it. I cannot read EZNEC format specs, not running that software.

Well that #4114OCF is designed for windom Off Center Fed dipoles.
The #4114 (no OCF) is good for high power or the #4113 for 3KW
will save a few dollars and work well for ladder line fed dipoles.

My 88 ft doublet is fed with 300 ohm twin lead and works well with my
100 watts and with QRP.It keeps the broad side pattern 80 meters up
thru 20 meters. Longer doublets start to break up into multi lobes above
10 mHz. However they work very well. The secret is to get the center up
as high as possible above 30 feet even if the ends droop to about 15 feet.
I use a home brew 4:1 balun outside under the eves and about 15 feet of
coax into the station. I have a 50K resistor from each side of the balanced
line to a ground to reduce static noise.

From: ka9p@...
Topic: 32900 Message: 32923

I ran the old, original MFJ for a while as a reference antenna on 20 and 17 and was pleasantly surprised by its performance stateside compared to an R7 verticil, and found it was as good as equal to and as bad as 0 to 6-8 dbs worse than a 30 foot high dipole.

Which is really good for a meter sized loop. There is some really good stuff on the internet about homebrewing, and a decent loop with a motor-operated 20-25 kv vacuum variable is a project I'd really like to get around to, as the few guys I've heard running 500 watts or so to that type of loop in the western US have had very competitive signals into Illinois.

Good luck. Scott ka9p

Re 8: EZNEC files are in a secret format. NEC2 files are not.
I recommend NEC2 versions. I have attached one to this email, mostly
to see if it makes it to the list or is stripped by yahoo. I am trying
to discover if EZNEC can produce card images of its input specs, but
am hampered because the EZNEC manual is also secret. (Mr Lewellan threatens
non-users against downloading (and presumably, reading) it.)

I attach the NEC2 input for my sim of Br Schwartz's "Vertical with CP".
I've also attached a .png of the VSWR and Z plots of the run of same.

I do not have facilities to post images to "the web". No website will
have me.

> I think that if these are provided, us modelling geeks can duplicate your work.....

The NEC2 file would suffice for me.

This is the NEC2 deck, with most comments stripped.

Impedance is more informative.

> 6. Include the antenna view if possible. A picture speaks a thousand words hi.
> 7. Include the type and version of the software used.
> 8. Last, it is great if you go to the output toolbar and select the description and copy it into the text.

Re 8: EZNEC files are in a secret format. NEC2 files are not.
I recommend NEC2 versions. I have attached one to this email, mostly
to see if it makes it to the list or is stripped by yahoo. I am trying
to discover if EZNEC can produce card images of its input specs, but
am hampered because the EZNEC manual is also secret. (Mr Lewellan threatens
non-users against downloading (and presumably, reading) it.)

I attach the NEC2 input for my sim of Br Schwartz's "Vertical with CP".
I've also attached a .png of the VSWR and Z plots of the run of same.

I do not have facilities to post images to "the web". No website will
have me.

> I think that if these are provided, us modelling geeks can duplicate your work.....

The NEC2 file would suffice for me.

This is the NEC2 deck, with most comments stripped.

```

Why don't you check out WB3GCK's Pop-Up Vertical?
It can be used in the configuration your referring to.

Great comments from everyone. Thanks. I hope they serve as inspiration for those on smaller budgets.

Just one more comment: The doublet antenna as already stated in other feedback, requires a balun, to convert the balanced feedline, to an unbalanced feedline.

I cannot stress too much, the importance of a good quality balun. It is imperative that this component of your antenna, be the best you can build or afford. Balun Designs (I am not affiliated) produces excellent baluns, and will also take the time to answer your questions, and enquiries in a timely manner.

Do NOT buy anything you cannot look inside. I have seen sealed $50 baluns, sold on the internet, and described as a 4 to 1 current balun, turn out to be nothing more than a galvanized screw nail, with about 8 wraps of cheap coax. This is NOT a balun...it is not even a good RF choke!

Finally, an Elmer to me, once told me, that if you want to guarantee RF on the OUTSIDE of your coax, use a voltage balun. ....and if you want to avoid RF on the outside of your balun, us a CURRENT balun. I have only ever used current baluns, and have never had an RF problem. I cannot verify the truth of this argument, because I have never felt the need to try a voltage balun....

I live in Campbell/Los Gatos area near San Jose. I used an old AEA Iso-Loop antenna for twenty years as my only antenna, and it worked very well. For awhile I had a Butternut vertical also. The loop performed as well most of the time, sometimes better, sometimes worse.

The MFJ loop is about the same size as my old loop but it has a much better remote tuning system. The narrow bandwidth of the loops means they need to be retuned whenever you move frequency and certainly when bands are changed.

My loop was mounted horizontally about 4 feet of the ground so it was omnidirectional. You can mount them vertically for directionality but I never tried that.

The loops running at 100 watts need wide spaced capacitor plate spacings. The capacitor connection to the loop need to be very low resistance which means that just soldering a strap isn't a good idea. My AEA and the MFJ loops both weld the loop-capacitor connections. That is good.

The MfJ loop is expensive. I suggest if you get one save the shipping box. If when you get a more permanent location you can then easily sell the loop on eBay! They hold their value pretty well.

32933. Using a 43 foot vertical as a mast or vice versa

Trying to kill more than one bird per stone here and still keep the XYL happy.

Has anyone built a 43 foot vertical from those 4 foot aluminum/fiberglass military masts? You lose 3.5" as overlap between the joints, but by the time you get to 40 some odd feet you're either a bit short or a bit long. Using 12 pieces you end up with 44 feet which might be close enough. There are also fiberglass poles that you can interchange with the aluminum and what I would like to to do is use 12 of the aluminum poles as a vertical (44 feet) and then put 4 fiberglass poles on top of that and use it as a traditional mast for my vhf verticals. I'd like to use both of them at the same time as a remote base setup if possible but I don't think there would be enough separation to prevent front end overload. Going with a mast instead of a tower (which I have but isn't up yet) would allow me to have a tilt over base and I could paint the mast so it would be less noticeable.

Is this doable and does anyone know how much weight these military poles can support?

Thanks in advance

I have not. In any loop design even milli-ohms here and there add up to decrease efficiency. There are a lot of mechanical connections in this loop's design.

32937. Re: Vertical antenna modeled

Yahoo group: ham-antennas (2014)
Date: 2014-06-21 20:20:17 UTC
From: schwartzj22@...
Topic: 32905 Message: 32937

Dave,

I appreciate the feedback. I am new at this. I can send you the 4NEC2 file. My email is as per QRZ.com.

I used the Optimizer to optimize the counterpoise length. When I did the modeling, I only used one counterpoise for each band. I did not look to see the effects of having all the CPs connected at the same time.

When I get to do the actual outdoor testing, the CP will be perpendicular to the dipole. I hope this helps.

Thoughts?

Tks,
Joel – N3GSE

You're quite welcome. This is fun for me; I'm fairly new at it, too.

> I used the Optimizer to optimize the counterpoise length. When I did the modeling, I only used one counterpoise for each band. I did not look to see the effects of having all the CPs connected at the same time.

Ah, ha! I'll be running some sims myself like this then. I was running
all the CPs connected at once. That will certainly change Z and VSWR!

> When I get to do the actual outdoor testing, the CP will be perpendicular to the dipole. I hope this helps.

Gotcha. I may try then throwing in a dipole wire, just for fun.

> Thoughts?

That is "do able" ---but you need to consider the Aluminum - corrosion will destroy efficiency because Al oxydizes VERY quickly. And the oxide is a great insulator.

The other problem: When you get above about 35 feet, the Aluminum poles get real heavy, and will "fold" while you try to get it up unless you do it by lifting one section at a time.

When you get to 40 feet, that is one HEAVY pole.

I have both the aluminum and fiberglass poles here. The fiberglas will fracture if it gets any bending moment going. (You can't do a tilt up on them...) So it is a straight lift only type thing.

The Aluminum, at least at the 30-40 foot level WILL allow you to do the tilt up thing, but you will need a couple of people to help getting it upright...and do that with guy ropes and so on.

I have a fan dipole hanging from the aluminum pole in an inverted V for 40-20-10. It works acceptably. However, when it comes to a rotor those poles will twist all by themselves... Go for the $100ish 35 push up pole from Rohn. They have a ground plate for it, and you can (in theory) put it up in the air at the right length...again with guy ropes.

I'm going that way for a hex beam I'm putting together for 20-17-15-12-10-6.... With a small TV type rotor for the antenna itself.

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

Hi All, since I live in an HOA, antennas are not permitted, LOL. I'm using a real 38' flag pole, think the tubing is 2 1/2" dia. It is mounted to my wooden deck and I have a piece of 6 guage wire about 5' long attached to it and the other end of the wire is attached to my sgc-235 atu. Have a field of radial wires attached to a copper stake about 7 1/2 feet in the ground and the ground wire from the atu is attached to the rod. The wire from the atu to the ground is about two foot. I can tune just above 2 to 30 with no problems. The flag pole is in sections and each section has been coated with anti-oxidant and fastened with stainless steel screws. Before the ?'s pop up, i'm currently a Tech but involved with the Coast Guard Aux and starting with Mars and have tested the antenna on most freq's because of them with no problems. I do know this is a compromise antenna, but it seems to work well for me as I have made many contacts from all over. I use NO guys on this flag pole. One might be able to put a fiberglass pole on top to use for whatever.

I also use those aluminum / fiberglass poles for all other sort of antenna's / supports. The fiberglass ones can be heavy and there are two types of these poles. The old ones have no reinforcements at the top or bottom, the new ones do and the new ones are thicker. As has been mentioned, guys on them would be the way to go.

Good luck, I’m having fun with the stuff I try,
hope you do as well.

Subject: Re: [ham-antennas] Using a 43 foot vertical as a mast or vice versa

Not sure this counts, but I am in the midst of erection of a 43 foot S9 vertical. I was unsure of how it would all work, but so far so good. I need to drive the galvanized 1 1/2 inch steel pipe and measure it. Assembly was a snap. By Monday I should have it up

Subject: Re: [ham-antennas] Using a 43 foot vertical as a mast or vice versa

I built a cobweb antenna and put it on push poles at 44 ft. I use 3 guy wire system at two points for 6 total guy points and have had no issues at all. I put it up last summer and it

surveived the winter just fine.

So with reasonable guying I think you would have a good shot at making it work.

The key for me was how to slow add sections and extend the guy wires so it was supported at all times.

Subject: [ham-antennas] Using a 43 foot vertical as a mast or vice versa

Trying to kill more than one bird per stone here and still keep the XYL happy.

Has anyone built a 43 foot vertical from those 4 foot aluminum/fiberglass military masts? You lose 3.5" as overlap between the joints, but by the time you get to 40 some odd feet you're either a bit short or a bit long. Using 12 pieces you end up with 44 feet which might be close enough. There are also fiberglass poles that you can interchange with the aluminum and what I would like to to do is use 12 of the aluminum poles as a vertical (44 feet) and then put 4 fiberglass poles on top of that and use it as a traditional mast for my vhf verticals. I'd like to use both of them at the same time as a remote base setup if possible but I don't think there would be enough separation to prevent front end overload. Going with a mast instead of a tower (which I have but isn't up yet) would allow me to have a tilt over base and I could paint the mast so it would be less noticeable.

Is this doable and does anyone know how much weight these military poles can support?

Thanks in advance

Joel

Not sure if this helps.
I just bought the S9 V43 43' Vertical Antenna - CLOSEOUT. From Cheap Ham. on sale for $125.
Have not put it together yet, but it looks well made and with some guying could probably support your needs.
Good Luck

I’m going buggy trying to figure out how far the base of the antenna will be. I had it once but have misplaced it. if the center pole is A and one leg of the antenna is 70 feet and that will be B so with the base being C how do I calculate the distance from the pole to the ground with the angles being 60 degrees. Not too sure I worded it correctly. I guess its an isoleces triangle

Add a 1:4 balun to your tuner and it will do ladderline

If you canb not find a match on a higher band or if it is a bit tricky to tune just add (or shorten) a few feet of ladderline and then try again

Nearly all manufacturers of tuners build their tuners that way (adding a balun to one of the outputs for ladderline) ,,, so why not do that on your tuner?!?

You also can add the tuner outside with a few feet of coax between that balun and your tuner in the shack (sometimes called "remote balun")

On some rigs with a good built-in tuner you also can stick that balun at the rig (and use the internal tuner with that balun to tune ladderlimne fed antenna)

With a bit of "calculating over the thumb" you can easy see what antenna length and what ladderline length gives a higher or lower impedance at the shack end

So ... there is no "magic" behind using ladderline

Well it is worded rather oddly but if I follow:

Pole is "A", leg of antenna "B" then from top of pole to ground would be "C".

Arranged more usually: Pole is "A", antenna leg is"B"(and would be the diagonal),and the length from pole to end of antenna "C".
Thus "B" squared would equal "A" squared plus "C" squared. or since you are looking for "C": C sq = Bsq minus "A" sq.
This assumes a 90 degree angle pole to ground and 45 degree at top of pole and at antenna to ground.

But you stated 60 degree angles? well then, if the angle at the top is 60 degrees, the angle at the antenna to ground will be 30 degrees. Therefore the distance from the pole to the ground end of the antenna will be 2 times the pole length.
Or if the angle at the top of the pole is 30 degrees (ground end of the antenna wire is 60 degrees) the distance "C" will be one half the height of the pole.

Hope this helps

Pole is 30 ft. A so from ground to top of pole is 30 ft. The pole will actually be 40 ft with the ends tied to a 10 ft pole so nobody comes in contact with the antenna. The length on each side will be 70 ft and this includes the insulators and guy rope. I would like to make the angle at the top of the pole no more than 120 degrees and no less than 60 degrees.

It was very helpful. At one time I had this all figured out

I have a telescopic fiberglass mast (http://www.mgs4u.com/Antenna-MK-6-HD.htm http://www.mgs4u.com/Antenna-MK-6-HD.htm) that I need a better way to secure to my house. I have soffits that overhang 25" from my cinder block/stucco exterior walls. There are rain gutters which stick out another 6".
for my metal mast, I used a 6" stand off bracket and secured it into the fascia board, but for this project, they won"t work too well because the fiberglass is 2.5" OD at this point.

Has anyone ever used any of that unistrut / superstrut to manufacture something to brace masts to the fascia? I am not mechanically inclined, so any advice would be extremely appreciated.

the intent is to secure the mast to the fascia, but the base will be secured with some big angle iron, into cement, and the pipe clamped to the angle iron. The top of the mast is guyed at various levels.

thanks,
Kevin

You will have lower loss (and maybe a better match) if you place the tuner closer to the antenna ... or better say ... use a SHORT coax to the balun

In my fc1000 (mobile tuner by yaesu) I had some spare room to add the balun directly IN the case ... with a short jumper from output to the balun I can use it as "normal" (for a vertical against ground) ... or with ladderline

And ... when tuner does not find a match with a given length of antenna and ladderline ... I just add (or shorten) the ladderline a few feet and try again

Adding a balun (or exactly a choke) to the INPUT of the tuner helps to suppress common mode current

And then also added some coils (chokes) to the control and power lines

So then the tuner is floating rf wise ... and only the antenna does radiate and not the coax to the tuner or the ladderline

... hope that helps you a bit

Greetz

And the chassis and case of the tuner is therefore RF-hot. Grounding the
tuner case then grounds 1/2 the signal, right? So one must allow it
to float.

Floating an asymmetric (i.e. typical, "unbalanced") tuner to get
symmetric ("balanced") results is quite a valid approach, and is used
by some designs, both commercial and amateur. But for safety, putting
the floating chassis inside another (grounded) cabinet, on standoffs,
with insulated shafts to all controls is part of the drill. I think.
At QRM power, it would seem to be unavoidable? Even at 100W?

I am somewhat mechanically inclined, I built my own tilt over tower/ antenna supports.
http://i1102.photobucket.com/albums/g453/KD0ZZ/TiltOverB-1.jpg

also several pictures of it in my album.

Also a small tilt unit I built 30 years ago,

http://i1102.photobucket.com/albums/g453/KD0ZZ/Tilt2.jpg

still in use today for test antennas

You can even build a wooden tilt antenna support if you have a little feline help

http://i1102.photobucket.com/albums/g453/KD0ZZ/Multi%20Band%20Vert/MBVert005_zps78008c01.jpg

Unistrut would work fine , they have nice little 45 degree angles to build a support triangle with. My worry would be the strength of you fascia board structure when you get a wind load.

Fc 1000 has a plastic case :-) so the only "hot" part is then the ground screw of the tuner (that is only hot when ungrounded!!!)

I used a choke on the input ... but when you ground the tuner at an antenna base that does not hurt ... so you can do both (grounded and ungrounded loads)

I’m planning on putting the Balun close to where the radio is located just inside my window. Coax will be about 6 ft.

73, WY6L

From: mailto:ham-antennas@yahoogroups.com
Sent: Sunday, June 22, 2014 2:15 PM
To: ham-antennas@yahoogroups.com
Subject: AW: AW: [ham-antennas] Simple Anternnas to get you started.

You will have lower loss (and maybe a better match) if you place the tuner closer to the antenna ... or better say ... use a SHORT coax to the balun

In my fc1000 (mobile tuner by yaesu) I had some spare room to add the balun directly IN the case ... with a short jumper from output to the balun I can use it as "normal" (for a vertical against ground) ... or with ladderline

And ... when tuner does not find a match with a given length of antenna and ladderline ... I just add (or shorten) the ladderline a few feet and try again

Adding a balun (or exactly a choke) to the INPUT of the tuner helps to suppress common mode current

And then also added some coils (chokes) to the control and power lines

So then the tuner is floating rf wise ... and only the antenna does radiate and not the coax to the tuner or the ladderline

... hope that helps you a bit

Greetz

Sigi

Dg9bfc

Ps a friend from me just erected (with my help) a ladderline fed doublet with an autotuner in his attic ... ladderline from there to the doublet ... works superb!!!

What is a good spray on coating for ladder line?
Something to lesson the change or effect when the ladder line gets wet ?
Any recommendations?
Thanks

I am guessing you mean the "window" line ... right?!?

I have seen that somebody took a punch (and scissors) and made the holes (windows) bigger to lessen the effect of rain on the insulation (that would also lower the loss somewhat but that is out of the question here)

Maybe some silicon spray or wax spray could help ... but I do not know exactly ...

You always tune the antenna at the shack end anyway ... and I do not think that a few drops of water will take out your tuner settings toooo much

Here the tuning does not change much when it rains (so the ladderline becoming wet is not the problem) BUT ... AFTER the rain the tuning changes cause the ground below the antenna becomes wet (changing conductivity)

But I only see that influence in very dry summers (cause in all other cases the ground here is wet even if it has not rained for weeks)

Why not PVC pipe little fish line at to and 1-1/2 cap pinch the fish line with cap it's in the PVC pipe and you can make or drill a hole in the top of cap and put a rope at the top to hang it fill the hole with silicone so it don't leak or fill up with water.

32961. Re: Using a 43 foot vertical as a mast or vice versa

Yahoo group: ham-antennas (2014)
Date: 2014-06-23 06:51:38 UTC
From: k9jfk@...
Topic: 32933 Message: 32961

Hi Joel,

I purchased the fiberglass poles a couple of years ago with just such a project in mind. After laying them out on the ground, measuring, weighing, and just "thinkin", I abandoned the idea as impractical for just one person. Had them out earlier this year to reexamine the idea and came to the same conclusion. First, it would be very hard for just one person to do alone, and second, it would require at least two levels of guy ropes, maybe three, to be safe. I believe the aluminum would present the same types of problems.

However, could it be done by one person? Yes, I think so, but it wouldn't be entirely safe and would require a great deal of care. Once up, I wouldn't think one person could take it down safely without breaking it.

If you look around, there are some commercial alternatives that could be erected by one person because they are "nesters" and can be secured one section at a time while being raised. However, they can't be used as supports for other antennas.

I think the practical limit for working with the masts, either fiberglass or aluminum, would be about the size of a quarter wave on 40m... 30 to 33ft.

Other alternatives have appeared in ham literature over the years, like aluminum ladder masts and wooden "A" frames, but you'd need help there, also.

73, Jimmie, K9JFK

There is also a 2 part spray that is available at Lowes (big box home supply) and others.... You spray on part A.. wait for it to dry.. then spray on part b... at the end of that, you have a VERY waterproof environment that acts like a really strong rain-x...but FAR better. (spray on shoes? No mud.. spray on gloves, never get wet, well..other than from water that runs down your arm...)

Spray on hat? Your hair (if any) stays dry...

If it is like the commercial "hydro-phobic" coatings that I have used on broadcast antennas, satellite dishes, etc., which is the very best product this type available, it is quite expensive). These commercial brands only last for about 5 years and then must be reapplied.

It's a type of thin Teflon coating. But it does wear off in time, due to outside weather.

Has anyone tried that new awesome stuff from Rustoleum? The "Never Wet" Stuff? Seems like it would not only keep it dry but looks like ICE should also never ever be a problem too.

What is a good spray on coating for ladder line?

Something to lesson the change or effect when the ladder line gets wet ?

Any recommendations?

Thanks

Hi Joe, The Never Wet does not last more than a few weeks, then the weather and sun destroys its waterproofing properties. It also leaves a whitish gummy coating that is about as conductive as Mylar.
I use it to keep mud from accumulating on farm equipment surfaces, but it does not even last a full season (three months). On slick soft plastics it just slides off and will not coat because of the oils in the plastic.
Where it shines is on a four wheel drive tractor in gumbo mud, use it on the insides of the fenders and both sides of the wheels where you really do not care is there is a slightly gummy off color white coating, and it sheds mud for a few weeks, then it has to be reapplied.
The company will not return calls either!

About 3 years ago W6YJG/ZL2WW Carter O'brien wanted to build a monster curtain array. He asked me to investigate, by modelling, the evolution of an array using double extended Zepp elements, that would allow him to operate 40 through 10 meters. This project started with a single 1-1/4 wave antenna element fed in the middle and expanded to a 4 x 4 array. This took over two years to finalize into a 110 foot high 110 wide guyed tower configuration. Unfortunately, Carter went SK before he could see his dream come true. I have be released to share this investigation to those interested.

I am not aware that there is any real reason to worry about water on ladder-line.

I used 450 ohm ladder-line for years with an inverted-vee in Montana with up to a kW on it, and never had a problem that way. Water was of absolutely zero concern to me both theoretically and practically.

Perhaps where the air is laden with salt-water, that might be a problem, but it most certainly never was for me.

Try using ladder line as a shorted 1/4 wave phasing stub in a collinear array sometime....What an exercise in frustration and futility till I figured out what was going going ...even dew in the morning would detune the array.

Two years ago I built (per an article in May 2011 QST) several Skeleton Sleeve Multiband dipoles which employ ladder line as the radiating element. One side of the ladder line is a dipole for band (Lower) one and the other side (cut shorter) is a "coupled resonator" for another higher band. They worked well until it rained or snowed and then detuned badly . Again this like collinear array example uses ladder line in a HI-Q / high impedance situation where even minor fluctuations in dielectric cause big shifts in resonance

But Kens point is well taken in most situations where ladder line is used as the feed line you will unlikely be aware of the changes in loss or antenna tuner tuning during wet weather.

I feel I should speak in defense of the methods used.

First and foremost, the balun has nothing to add. Follow his math.
He correctly determined the Z0 of the line and correctly determined the
velocity and attenuation factors. It is an error to think that because
a VNA has a nominal impedance of 50 ohms, it is incapable of measuring
anything except 50 ohms. What good would such an instrument be!?

In practical use, the first thing ladder line does is head for ground,
usually, then proceed along near the ground -- less than one wavelength
at HF from ground. Handbooks say keep it above "touching height", i.e.
at about 3m or 10ft. That's in the vicinity of 1/4 wavelength or less
for frequencies less than 30MHz. The ground is in the near field of
the transmission line for probably nearly all amateur applications,
from feed point to entrance to the shack.

I have the strong suspicion that 2ft is fully adequate to reduce ground
losses to negligibility. Two feet is a distance cited in handbooks for
keeping balanced line away from "earthy" objects. If you feel this is
"too close", I counter by saying: this distance is within standard
practical amateur experience.

The author might have repeated one set of measurements at, say, 4 and then
8 feet to verify this. I am not sure that the effects follow an inverse
square law, since the earth is an infinite plane. I dimly recall that
the field around a charged wire at a distance from an infinite plane of
charge (a capacitor made of wire and a plane) does not obey an inverse
square law, but varies with the first power of the distance.

[takes off amateur physicist hat, puts on professional chemist's]

My chief criticism of the experimental series is in the nature of the
water used; It was rain water, collected and allowed to stand in a butt

(US: barrel) of unknown provenance and composition. Think "acid rain" here, too, which is typically due to dissolved sulfur gasses resulting in dissolved acids, sulforous and sulfuric, commonly. Other industrial waste gasses can dissolve in rain water, and solid matter ("dust") often serves as a condensation locus in the formation of raindrops. Also, rain barrels are intended to catch runoff from rooves, rooves are made of asphalt, minerals, tile, lead, tin, zinc, iron and other stuff, even straw and dirt. Then there is "salt air", saltwater entrained by the wind and passing for rain in many coastal areas.

Rain water varies a great deal in its content, containing solid and dissolved matter, both organic and inorganic (it was in a barrel, too. What lived in the barrel). The rain, in falling, tends to scour the atmosphere, and even standing water can absorb or release dissolved gasses. These are non-trivial sources of conductivity, and rain water and distilled water are hardly synonyms. Even commercial deionized and distilled water is problematic in certain physico-chemical measurements. Elaborate apparatus is used to purify such "pure" water, often multiple distillation steps from treatment baths of strong oxidizers, using quartz apparatus, and carefully degassing the product. (CO_2 is a problem, you can't just let H_2O sit in contact with the air and expect to later find pure H_2O; dissolved CO_2 decreases pH and increases conductivity). Storage in plastic may be either excellent or disastrous, depending on the plastic and its history. (We have all tasted plasticky water at some time or other.) Storage in metal is typically problematic, too. Glass (some formulas) or fused silica (slang: quartz) is great, if it has been rigorously leached with acids and steamed for fairly long periods. (Hours, perhaps). Yeah, this stuff makes a difference and one of the routine ways that chemists check for water purity is -- no surprise -- conductivity measurement; I'm not being nit-picky.

But I DO NOTE that using rain water *closely approximates practical environment*, which you claim the author ignored.

So what the experimenter might have done is to measure and report the conductivity of the water used. This is easy enough to do if you have a platinum conductivity cell but there are also more expedient methods.

I also question the use of an unknown wetting agent; dish detergent typically contains a sodium salt of a sulfonic acid, and is quite conductive. (There are other kinds of detergents, some ionic, some not. See wikipedia.) Ethylene glycol, used as a wetting agent in photographic processing, is much less conductive. Since photography has disappeared from our world, Eastman Kodak Photo-Flo is no longer available in every small town. Alas.

So using detergent was an error, and we can't know whether the effects noted were due to "wetter" water or to dissolved sulfonates.

Note that I am using conductivity as a proxy for dielectric constant of the water. I am assuming that such a relationship exists.

Also, the experiment did not investigate weathering and soaking.
In practice, in certain climates, the line will be in effect soaked in water each day that there is dew or fog. There may then be freezing or heating. My part of Pennsylvania regularly has "freezing rain", "hoarfrost", "graupel" and other such nastiness, and it must take its toll of plastic line. It might leach out plasticizer, I guess, leading to cracking (perhaps invisible) of the line and increased water uptake during the next cycle. Perhaps a length of line could be simply suspended in the air for a few years and the experiment repeated. Maybe there is a standard (ASTM or ISO) procedure for accelerated weathering that would be applicable.

On the whole, though, G3TXQ is to be commended for a careful and highly illuminating study, and a proper and gratifying workup of his data.

Good morning, Mel;

If you are counting responses, I have an interest in a curtain array. Mike stahl once operated from Saipan on a bluff at a former VOA station using a curtain array that had a tuner, and he was on 20 Meters trying to contact a DXpedition in the Galapagos Islands. When he put out his call during the pile-up, the HC8 station was impressed. He immediately stopped the handling of the pile-up and simply asked; "Who was that?" Mike responded, and the HC8 station told him that he literally had the loudest signal on the band.

A few months later, that old VOA station, and the antenna, was torn down. Rats.

Yes, I am interested in the curtain array modeling you did for ZL4WW. Please increment the counter.

Enjoy, and 73;

I'm not sure I follow you. What is it about determining Z0 and alpha
(attenuation factor) that is inherently balanced or unbalanced?

I suspect that big-bucks VNAs may well have isolated input/outputs anyway.

> XYL mows it to bits, anyone that runs some distance two feet
> above the ground's surface creates a hazardous situation for
> foot traffic, desired or not.
> (and risks it's damage from animal and foot traffic)

...for those reasons, and perhaps others.

I don't propose running any feedline at 2ft anywhere, but I question if feedline, be it coax or twinline, will have dramatic differences in properties at 2 ft vs 10 ft. Do you have data?

A test is meaningful if it can be reproduced and is based on some sort of engineering or scientific model of what is being tested. I think 2ft *sounds* adequate to measure *changes* of Z0 and alpha in the transmission lines being tested.

If one brand of window line showed significantly less change in attenuation than some other brand, would you reject the comparative usefulness of the data if both tests were run at the same height above ground, whether that height was 2ft or 200 ft? Do you maintain that the same feedline would show practically significant changes in attenuation at 2 feet and 10 feet?

We have to agree to hold different opinions until we win the lottery and buy a VNA.

Dave,
Sorry about that (from get smart /Don Adams)
I do however make my own open wire feeder,
I use figure 8 speaker wire , seperate the two wires , then using Rawl plugs and small electricians zip ties create the ladder line , by threading the tie through the Rawl plug, then securing the the wires at each end of the plug.
Cheers,
Jeff

I have a few dozen of these fibre glass tent poles ... going up to 10 or 12m is easy ... but far beyond that is difficult ... it is just getting a bit woobling

When I wanna go higher I have some sections glued together (2m elements instead of 1m elements ...

But you are absolutely right ... going higher as 10 maybe 12m is difficult with these poles

There are 2 ways of building a pole with these tent sticks

Either put up a smaller one and add elements from below (second person needed ... maybe a few other holding guy lines!!)

Or put them together on the ground (with guy wires already attached!) and then put it up vertical ... (a gin pole helps a lot!)

What is easy to do is ... use a tree as a helper for putting up a bigger pole ... add a rope and a pulley at the top of a short mast ... add elements from below and push it up close to tree ... tree limbs secure the pole from the sides somewhat ... and when the pole top is high enough in the tree you can use the rope to pull your dipole/fedline up there

(but a sudgun with ropes pulled over the tree could do the same thing ... right?!?)

32983. AW: [ham-antennas] spray on coating for ladder line

Yahoo group: ham-antennas (2014)
Date: 2014-06-24 12:59:46 UTC
From: siegfried jackstien
Topic: 32956 Message: 32983

For a vna that can do such tests at shortwave frequencies you do not need to win a lottery ...(it can be homebrewed!)

What about using the 450 ohms windowline ... and just make the holes bigger

So you have lower area where any water can change the loss or velocity factor of the line

Or in fact only let small spreaders and cut the rest away

Then the line would not change its loss or velocity factor too much ... reardless of wet, dry, frozen, whatever

....

But surely a real open ladderline is best :-)

32984. Re: spray on coating for ladder line, and Feedline Height

Yahoo group: ham-antennas (2014)
Date: 2014-06-24 16:23:27 UTC
From: Ralph Javins
Topic: 32984 Message: 32984

Good morning;

One very practical reason for keeping any feedline at about nine (9) feet high is the need to have clearance over any people who may walk under the feedline. This point is also mentioned in the ARRL Antenna Book and the ARRL Handbook.

While the minimum suggested height of two (2) feet above ground for a parallel wire feedline is sufficient to reduce any coupling effects to a manageable level, the practical considerations for people, dogs, and other things, should be factors also.

Enjoy;

32985. Connecting wire to insulator at the end of dipole

Yahoo group: ham-antennas (2014)
Date: 2014-06-24 17:48:07 UTC
From: peglegaf5o@...
Topic: 32985 Message: 32985

What is the proper way to connect insulated wire at the end of a dipole or windom antenna to the insulator?

1. I have heard of the use of small aluminum cable sleeve used to connect the wire together after it is feed thru the insulator or using copper wire to wrap around the wire. The wire is insulated, will the the aluminum sleeves or the copper wire change any of the characteristic of the antenna SWR?

2. I have seen it looped thru insulator and wrapped back around the wire towards the center of antenna.

3. I have seen it feed thru insulator and zip tied with the zip tie around the two wires and then the end feed back thru zip tie and then zip tie pulled tight and then taped over with electrical tape to keep the zip tie from deteriorating from the sun.

4. I have seen it feed thru the insulator and then the end of the wire striped and a small section just before the insulator stripped and then the two soldered together.

Where does the radiating point stop at the insulator?

Plans?

(In some of our cases, a lottery win is required for pretty much
everything over $50!)

> What about using the 450 ohms windowline ... and just make the holes bigger

I suppose the chief drawbacks would be:

* Z0 changes (lowered). But it's misrated already, should be called
"400 Ohm" line.

* Weakening the spacing would allow the two conductors to have inconstant
separation, an issue in the wind or at bends or twists in the line.

> So you have lower area where any water can change the loss or velocity
> factor of the line

No doubt!

> Or in fact only let small spreaders and cut the rest away
>
> Then the line would not change its loss or velocity factor too much ...
> reardless of wet, dry, frozen, whatever

I'd have liked to see a test of window line encased in an inch of
ice -- assuming it could be somehow supported!

> ....
>
> But surely a real open ladderline is best :-)

I think I agree. The 100-150mm spacing is a bit clumsier to handle
and might be heavier, depending on what is used for spacers and how
close together they are used.

http://www.ea4frb.eu/antenna-analyzers/sark100/Archive

SARK 100 ... homebrewed vnwa up to 60 megs

But ... you can buy these sark100 now ready built for around 60 euro in china (sark100) ... or with a different layout and powersupply (li-ion battery with chager) and with Bluetooth module added for around 100-120 euros (named "mini60")

```
>
> (In some of our cases, a lottery win is required for pretty much

All solutions do work!

Radiation stops IN the insulator (if that is the longest part from centre)

Wrapping around without soldering is used if you wanna have length to play
with for tuning

Soldering CAN be done but it is not needed

If you were worrying about wrapping the wire around itself at VHF or UHF, sure, it would have an effect. At HF and up through 6 meters, it is negligible, and ground capacitance and resistance and inductance and a whole slew of other things have far more effect. If you use an ATU, as many are today to fine tune an antenna, then it makes no difference at all. Most modern rigs (not all) have an internal ATU, and it is a good idea to use it, as most modern rigs do not like SWR much more than 1.2:1. With a modern rig, like many of the portable ones, such as Yaesu FT-857 and FT-897 and Icom IC-7000 who do not have an internal ATU, it is a good idea to get one. Bad juju to run without one.

I know the purists will say "only resonant antennas should be used!" And "you should never need or use an ATU". (Hey you kids, get off my lawn!). Sure. A resonant antenna on 20 meters, resonated for the center of the band, say around 14.225 or so, will approach 3:1 SWR at the band edges. With an old Swan 500, no problem. (Why my ol' 40 Ford would run circles around these modern cars! Maybe, but can you replace the engine when you blow it up?). With an Icom 7000 you will be buying finals. With a Yaesu 950 or 2000, it may not even be able to flatten out the band edges, especially on 15 and especially 10! Buying finals again.

What I am saying in my usual long winded fashion (sorry dear) is the a HF antenna through an ATU, it makes no difference at all.

From: Kenneth G. Gordon
Topic: 32990 Message: 32990

I must partially dismantle my tri-bander so it can be moved to another location for Field Day.

It has been assembled for at least the past 30 years, and works well.

When I "re-mantle" the various pieces, must I use some sort of aluminim antioxidant like Ideal's No-AL-Ox when I put it back together?

Would it make the electrical conductivity between the various bits more effective to use it?

Mark all the elements BEFORE disassembly. Just use a Sharpie. You do NOT need to use Noalox for Field Day; it will make a mess. But, before you put it back up permanently, use the Noalox!

The answer is "most probably". Though it has been sealed up for 30 years, when opened it will oxidize some and you will probably see some surface deteriation. Clean the mating surfaces with a Scotchbrite green pad to shine up the aluminum and immediaytely coat with a thin coating of the NO-OX cream. It improves the conductivity, helps seal out moisture and makes separating the sections much easier. I have used it on all antenna aluminum since 1980.
You may not need it for Field Day unless you have trouble reassembling the sections. Be sure to mark each section as disassembled to help reassembly. Good to mark with a sharpie marker where each section was before disassembly. Helps to realign all the holes and clamps.

My only thought is that wrapping the wire several times through the egg insulator produces a very low static profile for corona discharge at high power. Also lessens the stress on the final wrap of the wire onto itself. The old Western Union wire termination. I always use 7 tight turns then solder.

Take a look: https://www.cedengineering.com/upload/Wiring%20Techniques.pdf

Ah, so. Thanks. It seems to resemble an MFJ-259 in capabilities.
I was talking about something more along these lines:

http://www.ebay.com/itm/Agilent-8510C-Vector-Network-Analyzer-/250908492570?pt=LH_DefaultDomain_0&hash=item3a6b4fc31a

USD3500, used. About twice what my car cost. Almost four months' income.
So as they say, "That ain't happenin', Bro'." Clubs might buy one,
but clubs would rather fit out air-conditioned vans so they can play
"junior policemen" at things like dog shows and garden walks. But to
each, his own.

It's not the next hundred that hurts, it's the many, many hundreds
that have gone before it. Yeah, I know, "sunk cost fallacy/bias".
But thousands wasted leads me to believe that the next hundred will be
a waste, too. Even so, I've already spent my allowance for this
month and next. (Bought a book, yet another book, overpriced, in the hopes
of finding wisdom. I should know better by now. The main lesson in
modern books is that there's a pile of money in publishing them.)

Thanks, you're right! Z0 goes as 1/sqrt(k) k goes down as plastic is
replaced by air as the dielectric. Vf would go up, too.

> Would it make the electrical conductivity between the various bits more
> effective to use it?

NO, it will make it "dis-assessable-able, which it may not be now.
It will 100% prevent the two mating surfaces from oxidizing which is the
conversion from aluminum to aluminum oxide, (the oxygen comes from water
aided by the miscellaneous chemicals and gasses dissolved in rain water)
aluminum oxide is also known as alumina. Alumina is what china and
pottery are made from. (AKA pure clay)
I recommend No-Ox wholeheartedly.

> turns then solder.

I always cut the two wires of dipoles 4 feet to long and I loop the
wire through the end insulators back, then I use small "split bolts" to
bind the near end to the wire about three feet back from the end, this
allows for easy and precise adjustments at any time. (move from one
band end top the other, then back) Make sure both half's are the same
length!
I also do a similar thing at the center insulator/balun using about
3-4 inches of wire at each connection, I always start by acquiring four
small split bolts when making a dipole. The "split bolts" will out last
us all.

From: siegfried jackstien
Topic: 32956 Message: 32999

Ok then ... if the sark is too simple for you (or you just need higher frequency range) ... then what about the kc901h???

Scalar nwa with colour display (you have a direct read-out / curve on a screen)

Around 900 bucks ... brand-new

Goes up to 3 gig

And it is a 2 port analyzer (so you also can test duplex filters etc.)

Not as cheap as the sark100 ... but does also not cost an arm and a leg (like a nwa form agilent, hp, whatever)

Dg9bfc

Now that one *is* a real temptation. Maybe the government will give out
Christmas bonuses to social security loafers such as me! (I am hopeful,
but not realistic.)

I'm waiting, though, probably, for something that is a card that plugs
into a PeeCee, runs under *n*x, has Agilent/HP capabilities, costs $39.00,
includes a dinner-date with a young lady of flexible virtue, etc etc.
(in declining order of feature priority. Something that would plug
into a PeeCee or better a laptop, would be nice. We own CPUs capable of
stunning performce (once freed of "browser duty"), 19" hi-res display,
etc etc, it would be nice it they were worked harder.)

Tnx,

Dave AB3NR

Also, don't forget that an 8510C VNA won't do you much good without some sort of sweep generator....(not built into this box like some of the newer VNA's).

I am sure it is impossible to create a VNA without a built in
tracking signal generator. The 8510 has it's.

Soldering stranded wire will usually make an easier place for the wire to break due to flexing in the wind.
Solid wire should be better if you are going to solder. I have built wire antennas for 60 years and just wrapped the end over the wire after going thru the insulator without soldering and had no problems.

Good information here. I agree.

My experience with a fiberglass mast only 25 feet tall and about 3 inches in diameter lifting a small 6 m cubical quad by walking it up was that it shattered very easily.

Best regards - Bry Carling

While I have not tried one of the lighter duty fiberglass masts, I have had extensive experience with the military Carbon Fiber mast sections that are about 4-1/2" in dia and about 4 feet long. Very Strong. I will put a couple of pictures and data sheets in the photo section. If you can find them, they are a excellent choice. I have one installed that is over 54 feet tall and was put up with a tractor using the bucket. The antenna in the picture is a OCF vertical dipole for 80 and 40 meters.

54 feet with these mil tent poles?? Wow that is real high ...

I would have been worried about wobbling when erecting ... but you have set
it up so it seems to be no problem ...

Ron:

I agree with you.

I used the 8510C on the job for several years and it definitely does not contain a built in tracking signal generator.

Topic: 32933 Message: 33013

Not tent poles, they were used to support a AZ radar/communication dish antenna and rotator at 100 feet. Look at the pictures for the data sheets.

33014. Re: Using a 43 foot vertical as a mast or vice versa

Yahoo group: ham-antennas (2014)
Date: 2014-06-26 13:42:39 UTC
From: jeffreyclay@...
Topic: 32933 Message: 33014

I setup 8 of the aluminum poles for my mast. I helped feed poles to my man on the ladder in a push-up fashion. I also had 3 friends feeding out guy ropes that were attached to the top and center of the poles. Before the guys were pulled tight it was a wobbly stick flexing ~3' at the top. Once trued up and tied down it withstands wind gusts of 50-60 mph during storms presenting itself as rigid.
I don't think going higher would be successful as a pushup with another level of guy.
Best of luck to you, Jeff KJ4RWH

Hello Raymond,

Is the modular house at that address where you live? Looks like a good candidate for a wrap around eve antenna??? What is the size of the perimeter of the eves? If that might be possible, no one would see it with #18 nickel plated copper dull gray wire. I have tons. I have done several of the eve antennas and the trick is to mount them on TV screw in stand off insulators. You remember the old 300 ohm twin lead standoffs? Antenna wire slips right through and doesn't touch any metal. I do a lot of antenna modelling and looking at the house, I need to know which room is your preferred operating space. I was thinking of a off center fed dipole for 40 meters 1/3 - 2/3. Would give you 40 through 10 meter coverage. As long as you don't run over 300 watts or so, the baluns and feed line can be quite invisible. Just a thought.

Because of the twisted pairs, it could be dicey. Ribbon cable used to
be a good choice also when it was readily available.

Bill wrote:

"Because of the twisted pairs, it could be dicey."

I guess it all depends on how you're using the cable.

If you tie all the strands together, at one or both ends, then I don't think it matters. It would be a bit like stranded wire, or maybe Litz wire. Should work just fine.

If by "individual strands" you mean unwrapping them down to the individual wires (to get eight times as much wire out of them), it would work, but the strands might be a bit thin for ruggedness.

If you had in mind making a multiband "fan dipole" (or whatever you prefer to call it) where wires of the same bundle are cut to different lengths, then I think it could be dicey. The very tight coupling between wires of a pair probably means you need to treat each pair as one, and not try to cut the two wires of a pair to different lengths.

Separate question: I'm wondering, has anyone used (or heard of using) CAT5 as an RF feedline? I read about this not long ago, where someone suggested it would actually work fine for HF. I've got my doubts, both for reasons of bandwidth and power handling.

Regards,
Andy

Slim Jims are not tuned when the measurements are "correct". You need to
move the feedpoint with a swr meter b4 soldering it.
Plus, check all connections. Mine (3 of them) all work fine.

33026. RE: [ham-antennas] role up slim jim

Yahoo group: ham-antennas (2014)
Date: 2014-06-27 18:14:37 UTC
From: Richard Schmuke
Topic: 33020 Message: 33026

Two things about a slim jim, the book measurements will only get you close, you need a SWR meter and/or a analyzer. I have made several J-Poles and slim jims and tuning is always a fine adjustment, then solder the wires and recheck.

Next , a slim jim cannot be grounded at the base like a J-Pole.

Subject: [ham-antennas] role up slim jim

i have made a role up slim jim ..... but it is worse receiving than my rubber duck on my hand held

I have all the measurements correct .... any ideas earth maybe ?

Many thanks

Heavens YES, it should have included CC&R's a long time ago.

I hope this bill passes because it's time the HOA's learned they can't bully people around by telling them what they can and can't do on their own property

Had a fellow here that tried building a 2 meter slim jim but had LOUSY reception, and trouble tuning.

when finally eyeballed, he had connected the feed backwards... (Center conductor to the short side...)

Reversed things, tuned, and got a 35 or 40 mile simplex session set up with the antenna up in the trees...

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

Two things about a slim jim, the book measurements will only get you close, you need a SWR meter and/or a analyzer. I have made several J-Poles and slim jims and tuning is always a fine adjustment, then solder the wires and recheck.
Next , a slim jim cannot be grounded at the base like a J-Pole.

A picture of your feed point would help. How is the coax mounted in relation to you lower part of the antenna? When making a wire or roll up slim jim I use a short run of coax with two very small alligator clips, find the sweet spot, mark it and install feed coax with ‘ugly balun, clamp and check then solder. My ground mounted slim jims always have a least a 1/4wl clear at the bottom with a fiberglass rod. I assume you are hanging it up high and clear underneath?

From: Chris Boone
Topic: 32784 Message: 33030

I used Cat 5 20 years ago as a 160m inverted V with all 8 strands tied together...worked like a champ....then made it into an 80 m full wave loop...granted it was tied off of a 250 ft microwave tower at work :) but it worked as it should (worse SWR was on 2nd harmonic, 40m, and that was only 3:1....the TS680 did not care and kept pumping out ok...I worked many 40m SSB contacts with it)....

The twist in each pair is to minimize crosstalk of the digital signal....using it as a feedline would probably not be the best as the pairs are twisted differently among the color codes and the line is NOT a BALANCED line for RF....it DOES work good for digital audio (like in AES broadcast use)....Zip cord (power or large spkr) would make a better feedline as it IS balanced and not twisted....however ladder line is not that hard to find OR make....

I wish you luck .... Im sure some day i will be in the same position !!!!!

I think the smallest possible 160M antenna would be a mag-loop or
helical loaded loop .... iv seen a (i think) 6.6' 80 through 20M loaded
loop ....
Its smaller than a C-band Sat Dish !!!

Anyways .. i hope it passes with out too many other things loaded
(attached) onto it ...

A 6' loop is not a "reasonable accommodation" on 160 or 80 IMHO. For
those bands two 120' towers would be more appropriate :-)

From: Scott Myers
Topic: 33023 Message: 33038

I used to live in a covenant restricted neighborhood. I move for many reasons, just one of which was to not have to get a papal blessing every time I wanted to do something to the property.

It will be interesting if this goes through. But like PRB-1, I wonder if each state would then have to pass their own bill to give PRB-1 real teeth like we did here in Ohio. I can see the lawyers licking their chops now at the money they will make.

I second that...I'm so tire of hearing about HOA's telling homeowners
what they can and can't do on there properties.
I understand there are people that leave there property looking like a
junk yard but CC&Rs shouldn't preclude anyone from doing what they want
on there own property.

While living in Houston, in a HOA addition. They restricted antennas to the usual TV antenna, no more than 10 feet about the highest point of the roof. Fortunately, my XYL was the president of the HOA and said to go ahead and put up my Hustler ATV-6. In reality, you really had to look to see it about the house. Don’t think I would have pushed for a Tri-bander at 30ft, what with the 50 foot yard width, and possible backlash…

33045. Re: House Bill Would Require FCC to Extend PRB-1 Coverage to Restric

Yahoo group: ham-antennas (2014)
Date: 2014-06-28 13:55:06 UTC
From: Glen Ellis
Topic: 33045 Message: 33045

.Guys,

Interesting thread.
I considered putting up a tower.
Called the HOA,
A rep came out and said there was "no rule on antennas",
"but, we will make one , now ".

So, I wrapped a 225 foot LongWire All Around the House,
and down the fence across the rose bush.
The counterpoise is tucked under the lap-board siding.
Works fine enough.
If you believe in Antenna Tuners,
there are many things you can do about Antennas.
.
I had a contact with a Ham who had loaded the Bottom End of a Rain Gutter DownSpout,
and was working DX. He believes in Antenna Tunners and any long piece of metal.
.
HOA activites make money for the real-estate company
because Home Owners are not business people and don't want to be.
As long as somebody is making money, the activity is here to stay.
.
If you don't ask, and don't tell,
and learn to hide a stealthtype antenna,
you can get on the air.
.

Glen Ellis

33047. RE: [ham-antennas] Re: House Bill Would Require FCC to Extend PRB-1 Coverage to Restric

Yahoo group: ham-antennas (2014)
Date: 2014-06-28 14:23:38 UTC
From: Joe Wolfe
Topic: 33045 Message: 33047

I would have tried to borrow a section or two of tower and set them up along side the house. Then when the HOA passed the no tower rule, you would have been grandfathered in.no law that prohibits something, can be passed that goes into effect retroactively.

A number of years ago, our neighborhood had a lady who was campaigning against my antennas (We have no HOA in effect..it died years ago!) You called a neighborhood meeting and the purpose was to pass rules, banning antennas. She riled against mine for 30 minutes, telling everyone how their property values were dropping, due to my antenna farm. Finally it was my turn.I told the folks assembled if they had read any of the Fire Departments' emergency evacuation and communications notices (We are in an earthquakes prone area). I asked one of the fire department's personnel to come up and read them.simply put, , they state that in a time of emergency, everyone should proceed, if possible, to my house as I would handle all communications, in and out, of our general area, in case all phone lines and cellphones were down. That opened a few of the newer residents of our area's eyes.I then stated, very simply, that they could pass an anti-antenna/tower law if they wished, but it wouldn't help, citing the old saw about closing the gate after all the horses has escaped.'nuther words.any rules they passed would not affect me, as they could not be made retroactive. Out od 40 people present, she was the only one who voted for rules restricting antennas.

.Guys,

Interesting thread.

I considered putting up a tower.

Called the HOA,

A rep came out and said there was "no rule on antennas",

"but, we will make one , now ".

Best to read the HOA agreement BEFORE you buy the house!

Mine has NO antenna restrictions and I live in a decent 15 year old neighborhood.
You can find them.

33051. Ionosokde charts and critical frequencies

Yahoo group: ham-antennas (2014)
Date: 2014-06-29 01:38:35 UTC
From: wa1rkt@...
Topic: 33051 Message: 33051

I'm just starting to learn a bit about how to read ionosonde charts like here:

192.52.62.251/latestFrames.htm

(odd that the link has an IP number instead of a domain but that's how it was provided to me...

I get how to read the critical frequency and the MUFs but that's about it... don't know what pretty much anything else in the lefthand column means. And, so far can't find a manual or help file that explains it all.

My main objective is to be able to find a reliable frequency, for comms out to about 75 miles or so, at any time during the day that won't get absorbed by the D layer. For example, today the critical frequency didn't rise significantly above 7 MHz all day. Theoretically 40 meter NVIS wouldn't have worked (it almost sort of worked, but comms were really difficult and I couldn't make out much of what was said) and 75 meters would have been (and was) absorbed by the D layer.

In addition to amateur use this will be used for MARS and CAP which have several frequencies to choose from between 75 and 40 meters. I'd like to know how to pick a frequency that's below the critical frequency but won't be absorbed down to nothing by the D layer. Can I get that info from the ionosonde charts?

Is it likely there'll be times when there is no such frequency, i.e. anything below the critical frequency will be absorbed by the D layer and I may as well pack up and go home and wait for nightfall?

Thanks...

Rick WA1RKT

I know I've seen a downloadable file or website or two with brief explanations of all the acronyms on those digisonde ionograms, but now I can't find it.

I'm pretty sure these ionograms don't tell you much if anything about D layer absorption.

From what I recall ...

"fo" refers to the "ordinary" wave, "fx" is for the "extraordinary wave. This has to do with the preferred(?) rotation of circularly polarized waves in the ionosphere, which is in one direction in the northern magnetic hemisphere and opposite in the southern hemisphere. If you send up a plane wave, it consists of CW and CCW components, but the two components react a little differently with the ionosphere, so they diverge. I think the magenta data is for the ordinary wave, and green is extraordinary wave. (Don't take the word "extraordinary" too literally. It doesn't mean anything unusual. I think ordinary/extraordinary are just old tech terms going back decades.)

It is technically not quite true that the critical frequency foF2 is the highest frequency that will reflect for NVIS. fxF2 is usually greater than foF2, and if you are able to get yourself between foF2 and fxF2 (which most people can't, unless you are military), the results are supposed to be pretty good Below foF2 you can have partial cancellation between the ordinary and extraordinary wave components. Above foF2 that cancellation goes away. A ham (now SK) told me how they used to chase that "sweet spot" between the two, when he did military communications in Britain, long ago.

F1, F2, and E refer to those ionosphere layers, of course. I don't think there is anything for the D layer in those plots. "fmin" is the minimum frequency at which a reflection was received, but sometimes that is just the lowest frequency at which that particular digisonde is allowed to transmit. (I think that's what I'm seeing right now.)

The abbreviations that begin with "h" refer to height above ground. You have effective and actual heights to deal with. The colored data is the effective height vs. frequency, calculated by dividing speed-of-light by half the time delay up and down. But the propagation velocity slows down significantly as the radio waves encounter the ionosphere, causing greater delay. So the actual height at which a wave "reflects" back down is much lower than the effective height. The lowest black curve plots the estimated actual height.

I *think* the "y" and "B" data have something to do with the shapes of the extrapolated curves through the data. Maybe not particularly useful except from a mathematical perspective.

Regards,
Andy

Chris wrote:

"The twist in each pair is to minimize crosstalk of the digital signal....using it as a feedline would probably not be the best as the pairs are twisted differently among the color codes and the line is NOT a BALANCED line for RF...."

I don't follow you there. I'd think the different amounts of twist shouldn't matter, and would only help. Each pair is balanced, as far as the copper is concerned; it's just up to you to feed it balanced too.

Since Ethernet *is* RF, and the idea of this cable is to keep the signals well balanced so they don't radiate and don't crosstalk and interfere, that particular aspect seems to be ideal for using this cable as a balanced feedline. The places I see problems, are attenuation, and power handling (neither of which is really a problem for Ethernet, since it uses a lot of equalization).

"Zip cord (power or large spkr) would make a better feedline as it IS balanced and not twisted"

I think everything I've read about zip cord recently, says that it is not a very good choice as a feedline, because it is lossy. Makes a great antenna, but could be a lousy feedline (which is not to say that you can't use it as such).

Regards,
Andy

The ionogram is the ultimate way of assessing short-wave propagation. It tells us exactly what is going on. To help interpret the ionogram, there are also a useful set of figures provided in the diagram which give us some very useful information. So... how do we interpret the ionogram to help understand HF propagation?

251.62.52.192.in-addr.arpa name = digisonde-1.haystack.edu.

Hope that helps. "haystack.edu" is the Haystack Observatory of MIT.

Just means that likely the web site owner self-hosts the web site (or
purchased a dedicated IP address from a hosting service). At one time I
could lease a dedicated DSL connection from Centurylink and then self
host my own web site if I chose (so my customers could download files
from MY server) . It was too expensive not to mention the operational
overhead (my personal time) and I later dumped Emabraq/CenturyLink
anyway because of their unresponsive and arrogant customer service. Most
web sites are hosted by a 3rd party and use a dynamic IP addressing (
from a block of addresses) to balance the data load across multiple users

Actually ZIP cord makes a good feed line at 80 and 40.
Loss is about 3 dB at 10.1 and 4 dB at 14.0 per 100 feet.
So short lengths are OK at 30 and 20 meters.
It is better than RG174 mini coax on antennas I have built.
And, using only one length of zip cord and splitting the end
makes an easy antenna build and continuous wire, no solder joints.
Fits easily in a ziplock baggie.

Andy>> "I don't think there is anything for the D layer in those plots. 'fmin' is the minimum frequency at which a reflection was received, but sometimes that is just the lowest frequency at which that particular digisonde is allowed to transmit."<<

So, theoretically, if I pick a frequency between fmin and foF2, I should be good to go, more or less, right?

Trouble is, with the ionosonde I'm watching (Millstone Hill, MA), fmin is always 1.00 and never changes, at least that's how it's been for the last couple of days. Seems like the "real" fmin isn't getting recorded in the list on the left. Unfortunately so far that's the only ionosonde I've been able to access that's anywhere near here (southern NH) which is my area of interest and so I need an ionosonde in this general area. There are a few others including one at Hanscom AFB, MA but they have not been accessible for the last few days at least. Hopefully they'll become accessible again.

Meanwhile, I see near the bottom of the chart, at about the 100-km elevation line, some magenta dots start showing up at about 2.5 MHz or a bit above. Would that be a reasonable indication of the minimum useable frequency? Seems not... 75 meters is dead right now, and being Field Day and all, I would have expected to hear some activity on 75 from contesters if no one else, so it does seem like the minimum useable frequency is somewhat higher.

There is another sort of reverse-S-shaped trace that begins at about the 180-km elevation and just above 4 MHz, and ends at the 600-km elevation line and about 7.2 MHz (which is foF2). Does that look like a more reasonable range from minimun useable to critical frequencies?

I asked earlier if there'll be times when anything below the critical frequency will be absorbed by the D layer and I may as well pack up and go home. I suppose that in conditions like that the ionosonde won't get any echoes at all and everything in the lefthand list will be N/A, right?

Jerry Hall, K1TD, wrote a comprehensive essay on this subject published in the March 1979 QST..

The Characteristic Impedance was found to be 107 Ohms at 10 mHz, falling to 105 Ohms at 15 mHz. Velocity factor was 69.5 %.

Zip is OK for a radiating wire, but fails as a transmission line . Los per 100 feet was measured at 2dB at 7mHz, increasing to 7dB at 28 mHz.

I hope this is helpful.

Again as I stated, from the article you referenced, at 80 and 40 it works
well.
There are better antennas and feedlines at 20 meters and above.

Cat-5 can be pretty cheap these days, esp. surplus, and is lightweight. It also has about the same impedance as zip cord (around 100-120 ohms), so if you parallel two of the pairs, the impedance is just about ideal for driving a dipole.

Andy

"192.52.62.251/latestFrames.htm

"(odd that the link has an IP number instead of a domain but that's how it was provided to me..."

The Millstone Hill (Haystack Observatory) digisonde is one of the older ones around, I think. But over the years I have noticed that its appearance on the web seems to come and go, often for long periods. I had an opportunity to ask the director of the observatory if he knew anything about that. I think he wasn't even aware they still had a digisonde (not too surprising since his duties mostly concern the main Haystack Observatory dish). The whole Haystack/Millstone Hill facility is somewhat spread out in a few different clusters, and the digisonde could be hidden among trees. My guess is that it's been running all the time, requiring very little human interaction, and either someone forgets to renew the registration on its domain, or it migrates to another domain and word doesn't get around to us 'casual' users.

So the IP address might be the more reliable way of accessing those digisonde plots. That's my guess, anyway.

Regards,
Andy

Rick wrote:

"So, theoretically, if I pick a frequency between fmin and foF2, I should be good to go, more or less, right?"

I don't know how useful "fmin" is. It's just saying that was the lowest frequency they heard their own echo; but keep in mind they don't transmit all frequencies, and the digisondes have pretty sophisticated signal processing which might pull their signal out even buried in the noise, where you couldn't hope to pull off a voice SSB or ALE contact.

"Trouble is, with the ionosonde I'm watching (Millstone Hill, MA), fmin is always 1.00 and never changes, at least that's how it's been for the last couple of days. Seems like the "real" fmin isn't getting recorded in the list on the left."

Last night when I replied, it was showing fmin = 2.35 MHz or thereabouts.

Most of the digisondes have frequency gaps where they don't transmit. Look immediately below the X-axis line and you'll see a few line segments; I think those are their gaps. (See the short blips at 5 and 10 MHz?) Millstone has only a few, but it looks like 1-2.2 MHz is blocked off.

"There are a few others including one at Hanscom AFB, MA but they have not been accessible for the last few days at least."

Hanscom *HAD* an experimental ionosonde or two, many years ago. I could be mistaken but I believe they do not anymore. I used to drive right past the antennas which probably were it, but the antennas were all gone the last time I went that way (Tinker Loop). Google Maps' aerial view shows just grass and an odd mowing/mud pattern where the antennas used to be. But Bing Maps' aerial view does show some antennas there. I don't know which view is newer.

Topic: 33051 Message: 33064

"Meanwhile, I see near the bottom of the chart, at about the 100-km elevation line, some magenta dots start showing up at about 2.5 MHz or a bit above."

These plots are updated every few minutes. I can't see what you saw.

"Would that be a reasonable indication of the minimum useable frequency?"

Unfortunately the plots don't tell you anything about either path loss, or S/N. I would guess that if the Millstone ionosonde can't hear its own signal, on a frequency where it is transmitting, then you won't be able to do NVIS either. That's about all you can say. It might not tell you when conditions are good.

"There is another sort of reverse-S-shaped trace that begins at about the 180-km elevation and just above 4 MHz, and ends at the 600-km elevation line and about 7.2 MHz (which is foF2)."

I'm guessing that is just telling you something about the electron density in the F1 and F2 layers. The data below the start of that curve might be due to reflections off the E layer, not very important.

NOAA has a website http://www.swpc.noaa.gov/drap/ that shows the estimated D layer absorption, when there is a solar or geomagnetic event in progress. Click on the maps to see them better.

"I asked earlier if there'll be times when anything below the critical frequency will be absorbed by the D layer and I may as well pack up and go home. I suppose that in conditions like that the ionosonde won't get any echoes at all and everything in the lefthand list will be N/A, right?"

Probably. I've never seen that happen. (Not that I check the ionosondes that regularly, mind you.)

But you might still get through even if you can't do NVIS.

Regards,
Andy

Andy>> "digisondes have pretty sophisticated signal processing which might pull their signal out even buried in the noise, where you couldn't hope to pull off a voice SSB or ALE contact."

Seems like a more useful tool would be something that shows conditions that the normal user (military, commercial, amateur) would see, i.e. if the digisonde can pull out its own signal, by magic, that's all very nice but it's unlikely to be a lot of help to normal users establishing a communications link.

I wonder if it'd be practical to put together a poor man's ionosonde with a Flex SDR and B&W "radiating dummy load" antenna. That could perhaps tell us something that an amateur / MARS / CAP communicator could actually use to good effect. Of course it'd have to switch from transmit to receive and be ready to listen in a few hundred microseconds. That might be asking a bit much.

33067. Millstone Hill (MA) ionosonde vs www.spacew.com/www/fof2.html

Yahoo group: ham-antennas (2014)
Date: 2014-06-30 02:30:58 UTC
From: wa1rkt@...
Topic: 33067 Message: 33067

I've been watching MIT's Millstone Hill ionosonde (digisonde-1.haystack.edu/latestFrames.htm) off and on for most of today, amazed that the critical frequency never rose much above 6 MHz all day.

Then a couple of hours ago it took a huge and, it seemed, almost instantaneous jump so that now, they claim the critical frequency is 8.35 MHz.

Yet when I look at the worldwide F2 Critical Frequency map at www.spacew.com/www/fof2.html, it claims that the critical frequency here (southern NH) is more like something under 5.5 MHz.

What am I supposed to believe?

OK FOLKS:

Here are the rules of the reflector : HAM-ANTENNAS
This file will be sent once a month automatically to remind all users.

1. Name calling (race, religion, politics, gender, etc.), is prohibited.
2. Telling someone they are ignorant (in any way, shape, or form), is prohibited.
3. Denigrating other races or minorities, or expressing POLITICAL VIEWS will earn you moderation or banning.
4. If you do it privately it is a private dispute. When/if it spills over onto the reflector, you will be moderated or banned.
5. Even coming close to these boundaries is to be avoided.
6. Banning/moderation will be used, with NO notification to the transgressor.
7. Civil chatter and Civil wordage is THE rule.
8. IF the Moderators are offended, then penalties will be applied.
9. There are two Moderators, EITHER can ban/moderate you.
10. Moderators ARE the final arbitrator of disputes, we hate bickering!
11. USE Private or Direct Emails to address your concerns to the Moderators, because public postings may likely result in penalties as above. !!!!
12. Use common sense. If you would be hurt or upset if you received what you are about to send, and you are intentionally meaning to do that, DON'T DO IT!

13. We ALL would like to enjoy discussion about HAM-ANTENNAS, nothing more.

33069. NEW Challenge Rest home restricted use HF antenna

Yahoo group: ham-antennas (2014)
Date: 2014-07-02 23:10:43 UTC
From: farrerfolks@...
Topic: 33069 Message: 33069

Ok, while this has been addressed under CCNRs, apparments dwellers, etc. This is more challenging. I have a VERY alert ham with a restricted use of the property, a 5 bedroom assisted care unit in a congested home environment, I recently got permission to put up a outside J antenna so he is on the air VHF, but sorely wants to get back on the air HF even at a VERY limited efficiency.

Conditions:

1. Single story home with perimeter wood fence, lots of trees, shrubs, etc.
2. Limited access to the side yard but a trench to the fence could be done, hint hint.
3. Antenna and matching, tuners out side must be nearly invisible.
4. Cost is limited with his condition.

SO, I envision a outside wire antenna, Probably a FAR endfed. All band Xcvr with ATU, Low power of course. Primary interest is 80/40 meters, naturally, didn't want to make it easy. I have used #18 nickel plated copper wire with success as it turns gray quickly. Maybe a end fed wire supported near the top the the wood fence?

A general discussion is appreciated, hate to see an old ham who wants to get back in isolated.....

I suggest the 9130 balun by Balun Designs(costs $50) and an 59 foot end fed wire.
Balun designs has a chart of wire lengths to use with the balun which is good to 300 watts.
So should work great at 100 watts or less. Of course longer wire will work better at 80 and 40 meters. Counterpoises can be run along the fence. Wire can be installed as inverted L if needed for extra length. Should be stealth but functional.

Another is the end fed wire and balun by the Hawaii group EARC which is also about $50 kit and $79 assembled.

I have a small yard 36 x 45 feet but I don't have the restrictions you Ham has .
However what about a non resonate loop around the house eaves feed with 300ohm /open wire feeder to a Balun, then to a tuner .

I have a similar arrangement but at a higher elevation and have found it to be better than the doublet i previously had.

another option would be to look at using the guttering for an antenna and setting up a ground system around the house .

just my 2 cents worth hope it helps.

That EARC end fed must have had a price increase. Mine was $50 delivered and assembled.

It has a 30 or 31 foot wire. Not sure how it would work on 75 but with 75' or rg-8x swr was below 3:1 6-80. You can get the stealth wire from wireman if needed. Something along that line will probably be your best bet.

Something a little better would be a remote tuner with a wire and counterpoise.

There is a Utube of a guy in New Jersey I think using that arrangement at his condo with his K2 and KX3.

I've heard of using screwdrivers and heard one on 40m.

At the very least, get him on Echolink.
I use that some in the truck from my iPhone. I have to swap trucks every day.

I don't get to check in here every day or even every week so get me direct if you want to swap ideas. If you were anywhere between Dallas,TX and El Paso,TX I'd loan you my EARC to try. Really all you need is a 9:1 Balun. They have a schematic and pictures on their website.

I could find the before mentioned video if need be.

Good Luck

Ok. I want to thank all those who offered comments. After conferring with the land lord, any antenna other than a single wire is out. No climbing on the roof, but eves are an open issue, maybe. No open wires that patients might touch. There is a copper water faucet near by. Ground???? Here is an interesting comment made, those darn birds are a problem and mess all over the back patio.....hint hint. I suggested a bird deterrent in the form of mylar metalized streamers that flash like they use in the orchards might be a help.....

How about a couple of very thin support wires with spaced streamers to keep them away????? He is thinking about it. They would be festive in appearance, hummmm .

So at least at this rest home for a old ham, it looks like a hidden feedline to a end fed HW with a 9:1 and a ground then feed up the plastic down spouts is a real possibility. The saga continues.

Thanks guys,

Mel, K6KBE

Date: 2014-07-04 01:33:44 UTC
From: Ed Simpson
Topic: 33069 Message: 33089

Several years ago one of our ham/Coast Guard Aux guys moved into a retirement home. He moved into a littlebungalow beside one of the three story residences and other bungalow's. We were able to put a 43' vertical with a sgc auto tuner at its base on top of the three story building. We ran the coax along the top of the roof, down the rain spout over to his bungalow. They had the Gardner trench about 4' to run the coax to a window. We used a bias T setup to get power to the tuner and he uses it all the time. I understand this is probably an exception and I don't know how he made it happen, but he is one happy person.

Good luck
Ed

Pretty much all of the systems that Alpha Antenna builds are suitable for HOA and other antenna restricted locations (ref. http://AmateurRadioStore.com http://AmateurRadioStore.com)

Unfortunately HOAs have a tendency to decide for themselves what's suitable and what's not.

The computer remote access to an off-premises and more-capable station won't work?

While he is still very much "with it" in conversation, he has problems with "complicated steps to execute" , just like me. ha. He does not have Skype or high speed internet access. Text, and emails are about the limit. darn. So I am trying to keep it simple. Here is the set up from what he tells me.

Older HF transceiver without ATU.
He can afford a ATU
Thinking about a OCF dipole so it won't need a hard ground, Land lord said no rods or trip over wires.
So EFHW is out

So, I wait to see what the landlord will allow and then go from there. Hey guys, this is what we are all possibly facing..... Thanks for the comments. This seems to be an never ending story.....

Can he put an antenna on the roof? perhapse a folded di-pole ... laid down on the -- well just over each edge of the top part -- so that it stradles the top, if its not a flat roof ... that would just leave getting the coax up there ... Not full HF, but something ...

A single long wire connected to a good 9:1 balun will work fine. Use the braid of the coax as the counterpoise and use a 1:1 choke balun between the coax and ATU to stop rf feedback. This will give a stealth working solution.

I am forwarding this for your info. The 9To1 and a 30 to 50 foot wire with a counterpoise along the building wall on the ground may work and be non obtrusive and no "trip wires".

Stu, KI6J, has been redoing his web site and, for now, it's sorta sparse looking but he has more of his balun kits for sale. E-mail him at KI6J@... and he'll letcha know all about the kit --- one kit is $13.00, two are $24.00 and three are $33.00. Great value (you decided which ratio you want - 1:1, 4:1, 9:1 - and Stu provides the info on how to wind it). With summertime upon us, time to dust off those portable kits and antennas - if you need a balun, Stu's kits certainly fill the bill and his support is top notch! Enjoy the days ahead with a quality QRP balun kit from www.betterqrp.com 72, Jim Rodenkirch K9JWV

You might want to try CQ100. Runs on all Windows versions. It's free for 90 days and then it's only 39.00 a year. You have to send them a copy of your license as it is strictly for hams. Just Google cq100 or go to www qsonet.com.

Here in the Central PA area We have some friends in Homes. Where we made designed antennas in Cloth Trees. And In Umbrella stands.

We have a dipole out the window and on the roof.

The one home a large one made a room off of the carpenter shop the Mouse house. Where they have 10 -15 school type desk in cubes for the residents.

They can bring their rigs from there old home. The water tower outside must have 20 antennas on it.

Remember it is the backup communication for the Home.

If there a Will there a way.

Sorry to hear that the landlord was so uncooperative ,
I have a friend at our Radio club who operated on a wire dipole which was strung around the inside of his rental property.
Over here we are covered by federal regs, similar to your Fcc, and are able to erect antennas in our properties , but rentals are at the landlords descrition, .
I wish you the best of luck with your endeavour

Magnetic loop in an umbrella stand ... only brought out when in use

... well hidden wire antenna with automatic tuner (INVISIBLE TO LANDLORD!)

I would not completely give up ... I would try to install something Very
WELL HIDDEN ... and then use it

And if it does not hurt the landlords eye all should be fine

I once worked a friend who'd just moved and was using a "GutterTron" ant in the CQWW. Yeah, the gutter and downspout fed against a ground-rod. Another friend loaded up the liner in his chimney, called a GutterTron.
I worked all over the country on 10 and 15 meters recently using a large metal window frame (5' x 8' picture window) as the antenna. I used alligator clips directly from the KX3 to two spots on the frame, experimenting with spacing. This is not described in the literature, but it worked. The ATU tuned up the window frame to ~1.0:1 on 20-6 meters.

The one eyed is king in the blinds :-)

Or in other words better do a bad antenna indoors as no antenna at all

33110. Putting up mast/pole. Need some suggestions

Yahoo group: ham-antennas (2014)
Date: 2014-07-06 15:54:41 UTC
From: hitekgearhead@...
Topic: 33110 Message: 33110

I am finally getting around to installing an antenna setup at our new house. (Our first as home owners)

I have decided to use my military surplus 4' camo net poles for the project. 8 sections should give me just under 30'.

I have already mounted one of my poles in a 5 gallon bucket of concrete. I have also ordered an 18" standoff to clamp the mast to the side of the house just as it clears the roof line.

I plan on guying my top section just below my antenna mounts, and this is where I could use a few suggestions.

BTW, I am planning on supporting a dual band VHF/UHF antenna and fan dipole or possibly a doublet from this setup.

First question: Would it be a poor choice to use 17ga aluminum electric fence wire as guys? Since I am not supporting much I figure it would be a decent choice, and I could use the leftovers for more wire antenna projects.

Second question: I plan on guying in four directions. (lets call them direction 1, 2, 3, and 4)
In directions 1 & 2 I have some trees I could anchor my guys to. No problem there. In direction 3 I have a tree I can guy to but it is quite close to my mast. The guy wire will make a much more acute angle relative to the mast in that direction. Do you think that would be a problem?

Third question: In direction 4 I do have a tree on the other side of the house I could anchor to, but the distance would be quite a ways. I would much rather tie the anchor to the roof at some point. I could make some kind of anchor block out of wood or metal but I am unsure about attaching directly to the roof. I don't want to compromise the roof. Then again, this isn't a 200' tower either, so maybe just a wood block screwed to the roof and sealed up with some roofing cement would be just fine.

Also, I guess if I used direction 4 for a wire all the way across the roof to that other tree, I could use that wire (maybe copperweld) as both a guy and the top of an inverted L.

Thanks,
Albert

Well you lost me as it weren't on, Sound good and planed out.

1. Guyed wire should be stranded, Aluminum solid will break quickly.

2. Using proper clamps and mounting hardware for the guy's if there not all at a 45 degree or matching who careers as long as there secure.

3. Paint can ? on the roof or at the base on the ground ?

4. If you are using stand-offs are you mounting part of it to the house and up a wall?

5. A total of 30 Ft your talking 15 ft. above the Roof for the guy wires.

6. And supporting the coax.

Let's try again

Richard

I would put up a pole on the roof ... even if it is just a few metres it gives you some height ...

Use the military tent poles (camo net poles) for you end points of your shortwave setup....

You can put these pole in the trees (using the trees as additional anchor points) ... that gives you a lot of height without much guying needed

... I would not use al fence wires as guy lines ...

Use Dacron rope instead

Al fence wires makes superb antenna wire ... but as a guy?!? Not good

I would put up the dualband vertical on the roof (short metal pole) ... and add a pulley slightly below it

Then you can experiment with any shortwave setup without the need to put the pole down

I would not use 17ga alum wire for guy wire. 17 ga is very thin and alum is far from a good guy wire. Nylon rope is OK for light loads, I use small cable. The direction with the acute would have to be the direction with the least wind load. Here in the middle of Missouri we have high loads from the west to south west and need strong guys in that direction. East and south east has less wind here, check your wind. A dipole can be incorporated into a support system.

Polypropylene rope is common , cheap and very susceptible to UV damage.
Nylon is listed as UV damage resistant as per US rope and cable ,

(http://www.us-rope-cable.com/rope.html) and easier to find at a local
store than Dacron. Dacron can always be ordered. I use nylon for dipole and
loop antenna support thru pulleys and steel for guys on my mast.

Rich Kd0zz.

Use Dacron not nylon ropes. Nylon is very susceptible to UV damage.

From: hitekgearhead@...
Topic: 33110 Message: 33119

Tanks for the input thus far gentlemen.

Since the general opinion on the fence wire is negative, I have no problem using wire rope (cable). Upon further investigation, I think that the typical hardware store 1/8" or the 6x20 wire used for TV antennas should suffice. (Unless there are other objections)

The roof mount idea is not so bad but I live here in Florida in a single story house with a fairly low pitched roof. So starting at roof height doesn't get me too much. Plus I already have one of my 4' poles anchored in a 5 gallon bucket of concrete. I figure that will make a stable base.

The stand off I mentioned bolts to the side of the house and will stabilize the pole at about the 9' height. That and the concrete base should get me off to a good start.

The only other question that I am still unsure about is the guy wire that has to go in "direction 4" toward the house. I guess I could screw a block of wood to the roof and then install an eye screw into that. Along with a judicious application of roofing cement should be adequate to keep it waterproof.

Additional suggestions appreciated.

You appear to have trees all around your house , you could put up a non resonate loop , with open line feeder and a balun to the tuner.
Put the VHF / UHF on the pole and if you want to experiment , add a couple of pulleys under with a loop halyard to raise and lower antennas(wire) rope yes Dacron or cheap nylon and replace each year

when using wire rope you have to be careful to avoid having resonant lengths .phillystran is a good guy line and being non conductive does not need to be be interrupted with ceramic insulators . should use a minimum of 2 guys . 3 is preferred , 33 degrees apart . DX engineering has an assortment of guy rings and cable .

In conjunction with my antenna mast/pole questions I also have questions regarding lightning arrestors. I am looking into a couple products from either Polyphasor or Alpha Delta. Those are fine for coax, but how does one go about protecting balanced line? Are there arrestors for 300 and 450 ohm line? Or do you just disconnect when not in use.

Thanks,
Albert

Polyphasor or Alpha Delta are OK, but they have no static bleed. I'd recommend Array Solutions or Morgan Mfg. (took over ICE production) for coax arrestors.

Morgan Mfg makes a balanced line arrestor.

http://www.kf7p.com/KF7P/MorganMfg..html

Weather protect any of this type of arrestor.

Lightning arrestors are fine. But the only real protection is to totally disconnect your feed-lines when bad weather approaches. I never leave the house during thunderstorm season with antennas connected.

I am not so sure that the disconnect idea is the best policy . I
thought so years ago. I disconnected every thing and secured the ends
of the coax away from the station. I had a new tower and antenna
farm that had been up three days . On the very top at about 75ft. was
an Isopole for two meters. Boy! did it work good ! Lightning hit that
ungrounded radiator of the Isopole and came down the coax where it
jumped to a metal ash tray (yes that was prior to my lung surgery) and
then to a screw on the rotator box . Then things got interesting as
the AC lines were carrying the charge. Evey thing in the house that
happened to be on bit the bullet. Freezer, Reefer, all cable boxes and
TV's . My lawn sprinkler just happened to be on . I now only use
antennas that by design are DC grounded and never disconnect. This
subject will bring out many contrasting ideas , sort of like should you
or should you not solder the shield when installing a 259 connector .

I secure my cables OUTDOORS. That way, any wayward animal that happens to be on the porch might get toasty (wandering cats...) - but the zap will be away from indoors.

I lived in Florida for years, and did computer repairs for a living. Lightning season made payroll for most of the year. ($10k in damage to ONE location--- the connections between the server and all the workstations were ethernet..and it picked up a strike next door and basically popped every device on the net.

(A direct strike there is something that mutilates electronics totally.. but the network cable acted like an antenna and simply fried things. Hundreds of thousands of AMPS and millions of volts will produce a zap that will totally mess up everything.

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

33128. Ground Voltage Potential - EE's please comment

Yahoo group: ham-antennas (2014)
Date: 2014-07-07 16:46:19 UTC
From: Scott Myers
Topic: 33128 Message: 33128

I've had a nagging little ground loop problem in my shack since I built on a house addition that contains my shack 2 years ago and am now digging into the problem. I started by breaking down the shack entirely and starting over adding one thing back in at a time. I decided to really dissect the ground system and see what and if I can find anything. I've tried to make sure this newest shack is set-up properly. Yes, I've read W5BWC, W8JI, ARRL antenna book, Low Band DXing, etc., and I understand the NEC rules and am aware of proper grounding techniques. This is NOT the first shack I've set-up.

Describing the set-up: I've got a tower 170' from the house with a large cadwelded lighting rod ring about 20' across with 2/0 copper cables; 6 rods to tower legs with a 7th rod interconnected with the ring for the lightning arrestor system to bond to. All feed lines (7/8" hard line) and control lines goes inside conduits to house shack entrance. I've got the typical service entrance ground rod mechanically bonded to 6 gauge solid ground, which is about 20' in a direct line from the shack entrance. I've got an RF ground system under the concrete floor of the shack consisting of 7 rods; 6 in a 8' circle with one in the center. They are all interconnected in a star pattern by 2" wide solid copper strap that is welded to the tops of the rods. The central rod has a 2" strap that travels up the wall to the shack entrance. There is another 4 gauge bonding wire that travels outside the house to bond the service entrance to the shack entrance that is approximately 40 feet long after it zigzags around the side of the house. The only thing I have not installed is a house halo ground and a buried ground wire from tower to the shack entrance, which would require a total of 1,000 feet of 4 gauge solid ($900 at today's prices). Note the problem I'm about to describe would not be changed by installing those grounding sub-systems and would only further the lightning arrestor system.

This next part seems normal. I'm measuring up to 0.4 volt AC difference in potential from the neutral pin to the ground pin when loading up my dedicated ham shack outlet with my computer and my linear supply just idling when measured at the power strip close to the load. When it is not under load and all plugs are pulled out of the strip but the strip is still energized, it measures zero potential AC or DC. This seems normal. As I demand more current, I'm going to have some voltage drop between the plug and the panel down the neutral wire. And since I'm measuring it at a point some 40 feet down a wire from the panel, some voltage drop must occur. And as the load increases, I would expect to see more and more voltage difference between the neutral pin at the load and the ground pin at the load, which does happen when I bring in a few more items in and power them. I'm guessing I'm pulling perhaps 2 amps with the load I have going so that seems to jive with 40+ feet of 12 gauge solid.

Here is where it gets weird. When I un-bond my RF ground from the central ground point at the shack entrance, why can I see the same 0.4 volt differential voltage between ground pin in the supply cord at the load and the RF ground reference strap which is just a mere 20 feet from the service entrance ground rod? In addition, I see a .34 volt DC difference between these same two points. When I take this same line and remove all load from it and measure it's ground pin to the RF ground strap (again, un-bonded from the central point) I measure 0.6 volts AC and DC potential. I am having trouble wrapping my head around this. I'm beginning to wonder if my RF ground system was broken during construction and I'm floating the RF ground altogether and it is simply not in contact with the ground, so the reading I am seeing is floating stray voltage. It's one theory. Or possibly the ground resistance is plenty high enough between the two systems and what I am seeing is simply normal stray voltage. I've just never seen that kind of voltage potential difference so close on a building.

Maybe I'm missing something or doing something wrong. Or it's just normal, but it doesn't seem so to me. Normally, the RF ground will be bonded at the central point at the shack entrance and you could never measure this difference. I'm just examining all the details.

Thoughts? I'm baffled.

Note that the RF ground is under concrete and a galvanized steel reinforcing mesh. It touches the concrete and the strap that comes up the wall touches the concrete. The copper itself is not prone to this in concrete, but the galvanized steel mesh in close proximity to the tops of the rods is, as the copper could be acting as a cathode. But it would be between the rods and the mesh, would it not? I shouldn't cause a problem, but I thought I would mention it.

I would talk to K3LR - He would have more experience in this line of field then most others. Putting a ground system underneath a concrete pad sounds weird to me.
Working in the electrical construction industry - with switch gear up to 500KV we normally just put down the grid and then cover it with a load of 2b gravel.
I would wonder what kind of galvanic corrosion it would cause with steel, copper, cement, galvanized steel and what ever else you have in your hodgepodge.
My question would be - why is the tower so far away from the shack?
Why not run a remote radio set up like the Kenwood TS 590 or 990 and have the radio right next to the tower in a separate radio shack?
My experience has been that if you are using a large amplifier into a non resonant antenna, using a tuner, that the rf gets into the computers and makes them to do weird things until finally they fail.
The large loss of voltage tells me that you have some kind of short somewhere in the loop.

Theory teaches us that in the world of lightning there is some simple steps that we take to ensure that we have minimum damage from electrical storms. In the grand scheme of things, your antenna farm is miniscule in size compared to the electrical grid in your neighborhood.
The only mistake you made was putting your 2 meter antenna at the top of the tower instead of side hanging it.
Most all lightning strikes comes in through the electrical service, not through the antenna. Unless you find the antenna laying on the ground - shattered into a million little pieces, lightning probably didn't directly hit the antenna causing the problem.
A dipole antenna, fed with ladder line is not to DC ground.
There is a multitude of different pass thru panels that can be used to run the wire through the wall or through the window that has terminals for ladder line.
The design is to ground everything before it comes into the shack, as is the Polyphaser.
Most professionally built radio sites runs on battery power, supplemented by a charging system using the commercial mains.
Get rid of the power supplies, convert to battery power, and most of your lightning issues will go away.
A more lightning prone area of the country might necessitate the use of multiple lightning arrest systems on the tower and feed line and station ground.

I didn't mean to just disconnect the cables and drop them near the radio. I have a feed through plate mounted in the garage where I pull the cables that run to the shack. Also, I think more lightning problems involve the AC lines then the antenna. I lost my entire station 2 years ago because of the power pole getting hit and and the surge getting into the ground side of the AC line. The antennas were fine. And a few items that were not grounded survived. So now I also unplug.

Jerry , You speak as one with experience . My two meter antenna had a word of caution I read later not to mount higher than 20ft. It was scattered all over the yard. I have taken another strike than came in on the wire.. That one made a bigger mess . I believe in Insurance & lost nothing . I recommend my approach to the possible problem. Chuck Wq5B

I've tried to e-mail K3LR on a couple of occasions and he never answered me. I figured he is too busy. But I haven't tried recently.

I put the RF ground system under the concrete pad because it is as close to the centralized ground point as one could possibly do and yet not interfere with the grading and outside work while I was doing the home addition. Yes, it sounds unusual, but it really isn't that unusual. It's just not common because hams rarely have such an opportunity to do it during a home construction phase. But the concerns with galvanic action with the steel and zinc are certainly quite valid. Copper itself is immune, but if within a few inches to steel it is a problem. In retrospect, I simply should have waited for the grading to be complete and done it outside the wall. It would have only added 2 feet to the ground run. I could still do that now and abandon the original RF system. Would cost me a couple hundred or so and some time is all. But if it turns out the current system isn't a problem, then there is no need make the change.

The tower is far from the shack because it is a big self supporting tower and had to meet zoning codes. It is not unusual for a tower to be away from a house. Guys with multiple tower (like K3LR) have many towers away from their house. (Guys like K3LR also have BIG ham radio budgets.) A separate radio shack is a nice thought, but not very practical from a cost and maintenance standpoint. It has to have its own power, HVAC, foundation, etc. Lots of $$. And then you still have ground bonding issue than one does in the house, so it doesn't solve anything in that area. All my antennas are resonant... and far from the shack. RF in the shack isn't a problem at all.

My ground loop issue that I mentioned rears its head in the form of the PWM from my Green Heron controller getting into the local audio in the shack (not on the air). I have figured out how to solve the problem. I am just tryign to wrap my head around the ground potential difference in this short distance.

I'm not sure what you mean by a "large loss of voltage". I'm only talking milliamps. More of a ground potential thing. Perhaps I am misunderstanding what you mean.

Subject: [ham-antennas] Re: Ground Voltage Potential - EE's please comment

I would talk to K3LR - He would have more experience in this line of field then most others.

Putting a ground system underneath a concrete pad sounds weird to me.

Working in the electrical construction industry - with switch gear up to 500KV we normally just put down the grid and then cover it with a load of 2b gravel.

I would wonder what kind of galvanic corrosion it would cause with steel, copper, cement, galvanized steel and what ever else you have in your hodgepodge.

My question would be - why is the tower so far away from the shack?

Why not run a remote radio set up like the Kenwood TS 590 or 990 and have the radio right next to the tower in a separate radio shack?

My experience has been that if you are using a large amplifier into a non resonant antenna, using a tuner, that the rf gets into the computers and makes them to do weird things until finally they fail.

The large loss of voltage tells me that you have some kind of short somewhere in the loop.

Check in the ceiling for where the roof beams are or the ridge beam and fasten into either of these for the 4 the guy wire
Have you considered the loop antenna
Mine tunes from 80 to 10 meters with a MFJ manual tuner

looks like you may have multiple ground points that are not connected together . all ground connections should be made to a single ground rod . if you have more than one it's likely there is a voltage difference between them . do not daisy chain them ,
multiples should all be bonded together with a heavy cable like welding cable or a heavy braid that is clamped .
do not solder , a lightning strike will generate enough heat to melt the soldered connection .

National Electric Code (NEC) now requires a method, i.e. Cadweld, etc.,
for connections in a grounding system. Clamping is considered
temporary. Soldering has not been allowed for many moons for AC ckts.
Please investigate and be safe!

another thought . there could be some defective line bypass capacitors in the equipment . recently have had some failures of them putting the full line voltage on the ungrounded chassis . I have older equipment that has standard .01 mfd 600 vdc paper caps for that purpose . there are better caps now that are designed for use in AC circuits . .

I have made progress on this subject. Turns out my ground system is fine, but I was able to make one point lower impedance by moving a connection point 2 feet. I did find fault with a switching supply and have replaced it. But thank you to those that commented.

Comments:

> From KD5PNT - "looks like you may have multiple ground points that are not connected together . all ground connections should be made to a single ground rod"

And all ground connections cannot be to a single ground rod as that would not meet NEC or pass inspection. I has to have a service entrance ground, lightning ground and RF ground, although the inspectors here do not care about the RF ground. There are many references to read on that subject. A complete high power station is going to consist of three ground systems, all bonded together in a proper manner. This has been tested very thoroughly loaded and unloaded and is not the problem.

> From Bill N7MOG - "National Electric Code (NEC) now requires a method, i.e. Cadweld, etc., for connections in a grounding system. Clamping is considered temporary."

Lightning grounds are all cadweld into 2/0 cable as is done with commercial installations. Service entrance ground is clam. Cadweld would be better, but it measures OK in resistance. This was still OK here in Ohio 2 years ago when it was installed and was inspected. The RF ground is all welded as well, but is hand brazed as it is copper rod on capper strap, which could not be cadwelded. Good safety reminders Bill. But that too wasn't the problem.

>From KD5PNT - " there could be some defective line bypass capacitors in the equipment"
Based upon further testing tonight, this appears to be where it is heading. The final part of the problem is PVM leaking into the audio system when the rotator controller is ramping. The problem goes away when I run the controller on a battery/inverter. I've got more detective work to do with this.

73,

The natural progression in amateur radio is to start out small, grow your shack with your budget and then go all out when you retire or hit the lotto.
Then when you get old, downsize to just what you must have to get on the air and eventually move into a rest home and loose all privileges except your handheld or mobile dual band UHF / VHF.

Unfortunately as buddy clubs progresses, more older people tends to migrate up to 160 and 75 meters.
I don't understand the fascination with nets and buddy clubs - but that is just my observations.

There is no law that demands that a rest home accommodates any individual when it comes to operating amateur radios and transmitters.
The two most logical solutions is to find a rest home that already has an established amateur radio community within - with their own antenna's and radios.
Or - relent and accept the fact that amateur radio usually is not wanted in a rest home environment.

Having people with pacemakers and electronic devices in use to keep people alive might be interfered with - with a radio transmitter and antenna in close proximity.

Many hams that operates 40 / 80 meters tends to have their amplifier hard wired to their light switch in their shack and they believe that they cannot operate unless they have 600 - a couple of thousand watts to get their signal out.

If there was enough room, it would be possible to put up an off-center fed dipole that would be resonant from 440 MHz to 80 meters - but you would need at least 140' of area and would have to have it at least 20' off the ground. Hy Power Antenna Company - is one source for reliable equipment.

The second thought would be to install a Hustler 5BVT and plenty of ground radials.

Third thought would be to install a 80 meter vertical antenna..
I saw a vendor a couple of times at the Butler Hamfest, but I cannot remember the name of the company.

The only other option is to move....

My location is at 1400' AMSL, the average terrain at my location is approximately 1450' amsl.
I have 10 antenna's in my small lot - 50' x 150'.
One tower - 30' with a Solorcon A99 mounted at the top - 38'.
Below that is a home brew 6 element - two meter beam.
Below that is a 6 meter dipole antenna, can also be used on 10 meters.
Below that is a Diamond Discone that I reworked to operate 2 meters with less than 1.5:1 VSWR and 440 - 460 almost flat 1:1....
Below that is a jib boom with a Off-center fed dipole antenna.

On the main roof of the house there is a Diamond V2000 at 36' and below that is a jib boom with a Barker & Williamson BWD 90 - folded dipole...
On the shed roof there is a Antenna's Direct XG 91 and a Winegard 8200U...

My shack has never been struck by lightning..
I however have been struck while walking down the sidewalk as a child.

Having access to equipment used in the electrical construction industry - Siemens, I have everything bonded, but don't have the Polyphasers in place due to a limited budget - waiting to get a hole dug and cement poured for the 40' tower - which will replace the 30' tower.
The 30' tower is just standing on its tilt plate with some rebar pounded into the ground about 3'....
Most antenna's are fed with Belden 9913F7, although I am going to replace some of that with LMR 400 in the future.

Having worked previously in the tower climbing / construction industry - I have seen lot's of improperly installed antenna's and stuff laying on the ground that should have been in the air.

The best ones are the Diamond X510 which always seems to get struck by lightning...

Dacron Kite String... who'd a thunk? I have used 3/16" Dacron Rope for years without a failure, but as I recall, it was a bit pricey. 500# test should do the job, and 500' for 20 $US sounds great! And at less than 1/8" diameter, it should be nearly invisible from 50' away!

Kevlar breaks down in UV, Dacron does not. Keep that in mind.

To: ham-antennas@yahoogroups.com
Subject: [ham-antennas] Putting up mast/pole. Need some suggestions

I am finally getting around to installing an antenna setup at our new house. (Our first as home owners)

I have decided to use my military surplus 4' camo net poles for the project. 8 sections should give me just under 30'.

I have already mounted one of my poles in a 5 gallon bucket of concrete. I have also ordered an 18" standoff to clamp the mast to the side of the house just as it clears the roof line.

I plan on guying my top section just below my antenna mounts, and this is where I could use a few suggestions.

BTW, I am planning on supporting a dual band VHF/UHF antenna and fan dipole or possibly a doublet from this setup.

First question: Would it be a poor choice to use 17ga aluminum electric fence wire as guys? Since I am not supporting much I figure it would be a decent choice, and I could use the leftovers for more wire antenna projects.

Second question: I plan on guying in four directions. (lets call them direction 1, 2, 3, and 4) In directions 1 & 2 I have some trees I could anchor my guys to. No problem there. In direction 3 I have a tree I can guy to but it is quite close to my mast. The guy wire will make a much more acute angle relative to the mast in that direction. Do you think that would be a problem?

Third question: In direction 4 I do have a tree on the other side of the house I could anchor to, but the distance would be quite a ways. I would much rather tie the anchor to the roof at some point. I could make some kind of anchor block out of wood or metal but I am unsure about attaching directly to the roof. I don't want to compromise the roof. Then again, this isn't a 200' tower either, so maybe just a wood block screwed to the roof and sealed up with some roofing cement would be just fine.

Also, I guess if I used direction 4 for a wire all the way across the roof to that other tree, I could use that wire (maybe copperweld) as both a guy and the top of an inverted L.

Thanks,
Albert

Have a guyed Gap Titan DX vertical that has been guyed with Dacron. Put
up in 1999, still there, still guyed with same Dacron.

Topic: 33110 Message: 33150

I'm putting up a SW receive antenna with 80# monofilament fishing line from Walmart. It is nearly invisible from 50' and you have to look hard to see it.

Jim, WB4ILP

Dacron Kite String... who'd a thunk? I have used 3/16" Dacron Rope for years without a failure, but as I recall, it was a bit pricey. 500# test should do the job, and 500' for 20 $US sounds great! And at less than 1/8" diameter, it should be nearly invisible from 50' away!

On Mon, Jul 7, 2014 at 8:59 PM, Geoff NW7GM geoff.nw7gm@... [ham-antennas] <ham-antennas@yahoogroups.com> wrote:

I would not use 17ga alum wire for guy wire. 17 ga is very thin and alum is far from a good guy wire. Nylon rope is OK for light loads, I use small cable. The direction with the acute would have to be the direction with the least wind load. Here in the middle of Missouri we have high loads from the west to south west and need strong guys in that direction. East and south east has less wind here, check your wind. A dipole can be incorporated into a support system.

Rich, Kd0zz

Subject: [ham-antennas] Putting up mast/pole. Need some suggestions

I am finally getting around to installing an antenna setup at our new house. (Our first as home owners)

I have decided to use my military surplus 4' camo net poles for the project. 8 sections should give me just under 30'.

I have already mounted one of my poles in a 5 gallon bucket of concrete. I have also ordered an 18" standoff to clamp the mast to the side of the house just as it clears the roof line.

I plan on guying my top section just below my antenna mounts, and this is where I could use a few suggestions.

BTW, I am planning on supporting a dual band VHF/UHF antenna and fan dipole or possibly a doublet from this setup.

First question: Would it be a poor choice to use 17ga aluminum electric fence wire as guys? Since I am not supporting much I figure it would be a decent choice, and I could use the leftovers for more wire antenna projects.

Second question: I plan on guying in four directions. (lets call them direction 1, 2, 3, and 4) In directions 1 & 2 I have some trees I could anchor my guys to. No problem there. In direction 3 I have a tree I can guy to but it is quite close to my mast. The guy wire will make a much more acute angle relative to the mast in that direction. Do you think that would be a problem?

Third question: In direction 4 I do have a tree on the other side of the house I could anchor to, but the distance would be quite a ways. I would much rather tie the anchor to the roof at some point. I could make some kind of anchor block out of wood or metal but I am unsure about attaching directly to the roof. I don't want to compromise the roof. Then again, this isn't a 200' tower either, so maybe just a wood block screwed to the roof and sealed up with some roofing cement would be just fine.

Also, I guess if I used direction 4 for a wire all the way across the roof to that other tree, I could use that wire (maybe copperweld) as both a guy and the top of an inverted L.

Thanks,
Albert

How UV resistant is monofilament fishing line? Brand is Eagle Claw.

They also have kevlar kite string for sale as well.

<ham-antennas@yahoogroups.com> wrote:

Polypropylene rope is common , cheap and very susceptible to UV damage.
Nylon is listed as UV damage resistant as per US rope and cable ,

(http://www.us-rope-cable.com/rope.html) and easier to find at a local
store than Dacron. Dacron can always be ordered. I use nylon for dipole and
loop antenna support thru pulleys and steel for guys on my mast.

Rich Kd0zz.

Use Dacron not nylon ropes. Nylon is very susceptible to UV damage.

James "Jim" M. Geidl, K6JMG
D.B. Cooper, you have a message.

I would not use 17ga alum wire for guy wire. 17 ga is very thin and alum is far from a good guy wire. Nylon rope is OK for light loads, I use small cable. The direction with the acute would have to be the direction with the least wind load. Here in the middle of Missouri we have high loads from the west to south west and need strong guys in that direction. East and south east has less wind here, check your wind. A dipole can be incorporated into a support system.

Rich, Kd0zz

Subject: [ham-antennas] Putting up mast/pole. Need some suggestions

I am finally getting around to installing an antenna setup at our new house. (Our first as home owners)

I have decided to use my military surplus 4' camo net poles for the project. 8 sections should give me just under 30'.

I have already mounted one of my poles in a 5 gallon bucket of concrete. I have also ordered an 18" standoff to clamp the mast to the side of the house just as it clears the roof line.

I plan on guying my top section just below my antenna mounts, and this is where I could use a few suggestions.

BTW, I am planning on supporting a dual band VHF/UHF antenna and fan dipole or possibly a doublet from this setup.

First question: Would it be a poor choice to use 17ga aluminum electric fence wire as guys? Since I am not supporting much I figure it would be a decent choice, and I could use the leftovers for more wire antenna projects.

Second question: I plan on guying in four directions. (lets call them direction 1, 2, 3, and 4) In directions 1 & 2 I have some trees I could anchor my guys to. No problem there. In direction 3 I have a tree I can guy to but it is quite close to my mast. The guy wire will make a much more acute angle relative to the mast in that direction. Do you think that would be a problem?

Third question: In direction 4 I do have a tree on the other side of the house I could anchor to, but the distance would be quite a ways. I would much rather tie the anchor to the roof at some point. I could make some kind of anchor block out of wood or metal but I am unsure about attaching directly to the roof. I don't want to compromise the roof. I don't know how you figure that one Dave.

Computers today are taught in Elementary school. Most school students are at par with what is being taught at the college level today.

It's the old people with the set in their ways attitudes that refuses to learn and refuses to change that holds the hobby back...

Young people has cell phones, that is basically a digital wireless device.
Any 5 year old child can run rings around even a 70 year old EE...

Young people also understands things called APS - Applications, and they are not afraid to buy one if it will help them out.

In the near future tower computers will become obsolete - only used for business applications and the lap top computer will follow. The Ipads and Ipods type devices - using Cloud Storage will over take anything we have today.,
We will be able to send digital messages - FLDIGI in the near future using nothing more then a cell phone, a sound card interface and a working HF radio.
A really intelligent person would probably go so far as to predict that it will also go wireless and use some type of BlueTooth type device - but I am showing my hand on that one by giving out idea's that people will be willing to pay for in the future.

It's the old persons attitude that you don't need to buy radios and you can use a handheld walkie talkie that gets us into trouble. When we reduce amateur radio to the use of FM repeaters and handheld radios - just because they are cheap and resemble a cell phone and just because there is no other investment with a walkie talkie - we give the impression that this is all that we do. What ever goes on - on the one local repeater that they can hit - is what goes on - on all repeaters all over the country.

When someone shows these people even what a simple 50 watt dual band mobile and a good piece of coax and a efficient antenna installed properly can do - they shy away from the hobby, because they were under the impression that it wasn't going to cost them much or anything to get on the air and the more equipment they have to buy, the less they want to get into the hobby.

Compound that with old hams that wants to sell their old radio equipment to them at a premium price, when most wireless electronic devices depreciates on a much faster scale then other consumer goods.
If the used equipment is non existent, or costs as much as new equipment, most people will not spend the money to upgrade to something better and will quickly leave the hobby as fast as they got into it.

WOW, some how this thread got completely off MY question.

OK, I will level the field a little. NONE of the modern technology was around IN MY TIME so we invented the next level. BUT we had the advantage of all of the learning of the earlier pioneers in electronics/radio. Those are the ones who had none of the modern stuff and figured it out individually. SO, What is different now? AND, how does that address my question about a new challenge in a rest home.....

Here goes from my soap box:

1. The children/adults today are given machines that do all of the manual work of connecting to the needs at hand and the outer world.
    Did you have to learn add,, subtract, multiple, and divide, on paper? The modern method is use the calculator, the result is the cashiercan't count out your change!!!!! Worse, they don't know how to do it manually.....Lost ability.

2. The children today do not know what components are used in the electronic devices they use. They just are not introduced into the real world of physics. Takes too much time and effort and they are easily distracted.

3. The current generation is a bridge from us old farts and the want to be better.., but don't know how.....
4. Some where along the line we sidetracked the learning experience of the fundamentals to one of instant solution without knowing how it is achieved.

5. So we have a generation of people that know what they want, don't have the background to figure it out, and blame those who don't just give them the answer.

6. The lucky ones are in schools that still have roots in basic learning skills.
7. The rest just don't care and don't exactly know where to go for help. God help us all.

Bottom line in this thread, and I wish the moderator to stop it after my entry. This question was a simple one of asking comments on a restricted antenna installation for a old ham. Nothing elaborate. Nothing hard to construct, remember the limitations of the land lord. Something simple. Thank you all for the contributions on that approach. I will get him a outside antenna. Maybe not the best, but one that satisfy his needs and the restrictions of the land lord.

Please in the future stay focused on the original question. Cheers.

Mel, K6KBE

Hi Mel,

As one of the old farts that has had to make the transition I want to say well worded. I commend your efforts to keep an old ham still on the air. Just because people get older and may need help with their daily living should not mean that they should have to give up all that they have enjoyed throughout their lives. Please keep us informed of the final solution to keep him on the air as this could help many of us down the road of life.

73 de K1EG

Mike

P.S. I ask them what would they do if they had no power and no calculator and usually it is the deer in the headlights response…LOL

(And it got stranger still after this odd assertion.)

Better let this thread fizzle out.

Nonetheless I am ready, in my 67th summer, to meet any five year old in single combat with a text editor and a compiler. The test will be /writing/ not /using/ some application.

OK, I will level the field a little. NONE of the modern technology was around IN MY TIME so we invented the next level. BUT we had the advantage of all of the learning of the earlier pioneers in electronics/radio. Those are the ones who had none of the modern stuff and figured it out individually. SO, What is different now? AND, how does that address my question about a new challenge in a rest home.....

.

<http://geo.yahoo.com/serv?s=97359714/grpId=12304712/grpspId=1705063108/msgId=33153/stime=1404866674>
<http://y.analytics.yahoo.com/fpc.pl?ywarid=515FB27823A7407E&a=10001310322279&js=no&resp=img> Hi Mel,

I gave some thought to your question and mentioned it on our nightly net and one of our local hams had an idea. If clubs that have club stations used rigs like the K3 or Flex Radios or similar then with internet access the member that ends up in a situation like that could use a remote radio with the internet to get on the air. I thought this was a great idea that radio clubs should explore for their members. Just my .002 cents (adjusted for inflation).

You are just like my two IT instructors at Penn State. The one - wanted me to learn C++ and the other was teaching HTML / HTML5..
The problem with this type of mentality is that it teaches data input, but it doesn't teach practical application - using a APP is much smarter than manually writing each line of code - CSS 9 Cascading Style Sheets) for those that does not understand what I am talking about.
Modern web pages - like what you are looking at right here - uses script, HTML - writing everything one line at a time and laying out the page manually and hoping that it is acceptable from one web browser to another - is not the right way to be productive.

As others has said, the Club is the key to amateur radio for most people.
Having a remote link that would allow you to use club equipment from a remote location would be a prime example on how to solve your radio issues.

Kenwood has a program for their TS 590S radio, as does Elecraft and others.

At one time K3WS - Tom, allowed club members (Cambria Radio club) to use his equipment remotely, but most of them could not comprehend the complexities of how to operate it, and Tom was using a non resonant antenna and an amplifier and his friends burned up his radio equipment. Maybe you could email Tom and he could give you some suggestions on how to build a station for this gentleman at your home and work it remotely from the rest home.

The solution to your problem is to use a resonant antenna.

Regardless of the height of the antenna, it must be resonant.

As with most antenna problems, I offer the same solution - the HY Power / off-center fed 80 meter dipole.
You will need about 150' of area, it does not matter if you put it up in a straight line or run it zig zag or a box configuration, as long as you get it up in the air as high as possible. I would recommend at least 10' off the ground .

Hi Mel,

That was why I mentioned the K3 they have what I call a dummy version of the K3 that looks exactly like a true K3 but has no guts in it other than the internet required components. It has the look and feel of operating a K3 but does it remotely through the internet. There are several large contest stations that are selling this service now to people that don't have mega stations, but it is for people with more money than brains because it is very expensive monthly. Some I have seen are $99 a month and 0.15 cents a minute, but if radio clubs planned for the future their members could reap the benefit.

All,

I might have just inherited a 1000' spool of AP6012J50 1/2" 50-Ohm hardline. Since I don't have an antenna farm currently and can only deploy low visibility antennas close to my house (stinking hoa), does anyone have any interest in something like this? Or should I just store it in my garage until I can buy a place that will let me put up a tower?

Thanks,

Number 1 - Considering using a few feet of the hardline for a magloop antenna. They are small - highly resonant.. and disguisable as things like plant supports and the like...

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

33166. which ferrite cores do I buy for my RFI ?

Yahoo group: ham-antennas (2014)
Date: 2014-07-10 14:41:13 UTC
From: ve3pie@...
Topic: 33166 Message: 33166

I am having RFI problems with my TV, sub-woofer, alarm system, and smoke detectors. I have been doing a lot of reading on how to wind chokes around various ferrite cores.
The main companies I see referred to are:
Fair-Rite
Amidon
DX-Engineering (Comtek chokes)
Palomar Engineers
ky-filters for telephones

the snap on type would be easiest for me. Are they as good as the non-snap-on type ?
I need to cover 80-10 meters. Should I select #31 ferrite material. Some articles refer to #43 ferrite material but as I understand it, is not as good for 40-80 meters.
I need some chokes for my RG-8 sized coax, and for some RG-8X sized coax, and for audio cables, and for 120vac power cords.

I need some concrete specific suggestions as to what to buy and from which company
thanks for your help - anyone please .

You asked for it;

You need to think about putting the ferrite choking devices on the
appliance's power and signal cords, not on your coaxes. *
You are probably experiencing overload from to great a signal level at
the appliances, moving your antennas up could also help.
* unless you have a lot of R.F energy on the outside of your coax/s
then you need to add balun/s.

Fred - you didn't mention what type of antenna system you have or how much power you are running.

A few years ago I was running a barefoot Elecraft K3 at 100 watts into a ground mounted Hustler 5BTV (vertical) with 40 various length radials. No RFI of any sort. When I put in a 500 watt linear, things got ugly. Our house alarm system (21 years old, wired) squeaked at me, the timer on the kitchen oven beeped, etc. Life was not good. I went around putting #31 ferrites on lots of things where I had access to them. The house alarm was nasty because of the many, many wires running from each and every window and door through the walls back to the control box. The kitchen oven was impossible - it is built in and there is no accessible power cord. I stopped a lot of the RFI but it was not a lot of fun, AND it got expensive with all the ferrites.

My problems were cured when I went to a different antenna. I now use an 88-foot long stealthy (HOA and CCR issues) wire doublet, strung through the trees at a height of 45 feet. No more RFI problems AT ALL, even with 500+ watts. I use the vertical as a "diversity reception" antenna on the K3, but I don't transmit into it.

Bottom line - you "may" be able to reduce or eliminate your RFI issues by placing ferrites on household devices, but I think you are going to have a LOT of them to install. And, what about your neighbors - what's the probability of your RF getting into their household stuff?

BTW - the vertical is fed with 90 feet of RG-8U and has a common mode choke at the antenna consisting of five turns of the feeder going through six of the 2-1/4" ferrite cores. The doublet is fed with 110 feet of 450-ohm ladder line and a 4:1 balun at the transmitter end. It works very, very well and causes no RFI to anything in our house or the neighbors'.

33176. RE: 40 - 10m cobweb antenna

Yahoo group: ham-antennas (2014)
Date: 2014-07-11 22:32:34 UTC
From: Geoff NW7GM
Topic: 33176 Message: 33176

Ron,

I have been in communication with Steve, G3TXQ, about a cobweb that would cover 40-10m and he suggested that the 30/40m elements be fed separately from the 20-10m section. He also suggested changing the ferrite core for the lower bands to a 43 mix while keeping the other balun instructions the same. His reasoning for the separate balun/feed is to minimize 3rd harmonic interactions and to allow the 30/40m wires to keep a more square shape. The spreader length for the 7 band version will be approximately 12' long.

I am currently in the process of building one of these and will post pictures to the group as I progress along.

One question I have for those that have constructed the single-wire version is, what waterproof box did you house your balun in? A part # and approx. price would be much appreciated!

By the way mine works real well and is not a compromise antenna. Mine is at 40 ft high and it out performs my fan dipole inverted v at 30 ft . Sent on the new Sprint Network from my Samsung Galaxy S®4.

I used a balun design unit that he makes for this application. Kd8nnu Don Sent on the new Sprint Network from my Samsung Galaxy S®4.

33179. Transco RF coaxial switches

Yahoo group: ham-antennas (2014)
Date: 2014-07-12 03:46:36 UTC
From: the_melzer@...
Topic: 33179 Message: 33179

Is there a web site that has information on Transco RF coaxial switches? I have searched and searched and can find nothing. Just picked a up a brand new 14300 which is SP4T and would like to see the manufacturers specs. The coils are 28VDC but no clue as to amperage, though I doubt it is much. Anyone have info on this device or know where I can find it? I want to use this to switch between antennas before it enters the building.

Thanks!

Mel W8QO

Hello!

I found this on a forum (http://www.eham.net/ehamforum/smf/index.php?topic=37106.0;wap2)

Dowkey has taken over the Transco line. They have a archive section there they may just help you with your questions on that switch. as far as price the guys are right most hams wont pay the retail price. but will take them if there free hi hi.

http://www.dowkey.com/

33182. 1/4 wave matching section and choke

Yahoo group: ham-antennas (2014)
Date: 2014-07-12 18:48:02 UTC
From: Geoff NW7GM
Topic: 33182 Message: 33182

Good afternoon everyone,

I am in the middle of building a single-band full wave loop and had a question about the 1/4 wave matching section and toroidal choke I'm going to be using...

My plan is to put the choke on the matching section of 75 ohm coax but I'm not sure if the coax that is wound in the toroid is counted as part of the matching section length or if the overall straight-line length is the correct length. Hopefully I'm explaining that well enough.

Could someone help me out with this?

Thanks,

As I understand the use of the choke, You can place it in either line.
The 75 ohm needs to have 20 feet of line wound on a 4 to 6 inch diameter
plastic drain pipe. This 20 feet will be part of the 1/4 wave length of 75
ohm line. Actually measure the line and tune it with ant bridge for center
of band and then wind 20 feet on the form.

Or, make the 75 ohm line and then connect the 50 ohm line which has the
last 20 feet would on the 4 to 6 inch form.
I usually put it in the 75 ohm line for 80 and 40 meters and in the 50 ohm
line for 10.1 and higher bands.

The 20' section would be dependent on the frequency, which I specifically omitted because I already calculated my matching section. My question was about whether or not the amount of coax that is wound in the toroid would be added as part of the overall matching section length or if the matching section length would just be the straight-line length (unwound coax - wound choke - unwound coax). BTW, the choke is coax wound in a ferrite toroidal core (ft240-61).

NO, the matching section is independent and part of the antenna and the choke needs to be at that junction whether it is coax wound on PVC or on a toroid. IMHO.

Gregg, i found some decent inexpensive electrical durable plastic enclosures at Lowes , just for comparison , i am sure homedepot and other hardware stores have some as well, these did not have holes to plug. mine i got was about 8.50, with mounting lugs to run screws thru attached, in electrical Section. i imagine the Ace Stores have them as well, Let us know what you find, 73s, AJ W5heh

Ps yes had rubber seal on opening lid that screws down, one could use wing nuts , with washers if needed for easy access.

The small ones for a transistor radio are made by flaring the larger end of tapered tubes and and inward rolling of the smaller end. Smaller tubes are pushed inside the larger tube sections, then a ball or something similar is crimped on the small end of the smallest piece, and a connection of some sort crimped on the large end of the largest section.
If you're looking to make a telescoping HF antenna, you will need to shop around the suppliers of EMT to find sizes that will slip into or over other sizes by using the charts they show on their web-sites.
You may be able to make a lighter version using wire inside sections of thick-walled PVC.
I had a chart showing the sizes and brands, giving all the dimensions for making HF beams, slotting the ends and fastening with hose clamps... but that computers hard drive crapped out and I haven't been able to find that chart again.
Let us know what frequencies you want to work with it and somebody might be kind enough to draw something up for you to try building.

Topic: 33166 Message: 33189

RFI can be caused by several things... corrosion at any point is probably the number one offender, check to make sure all your grounds are tied to one point to eliminate ground loops, all the screws and connections on all equipment are tightened, the antenna is at least 1/4 wave in the air. The feed-line to the antenna should not be radiating, usually not a problem when using good coax and a balun mounted at the antenna. Also check to see how close the antenna is to outside power lines that might be receiving your signal and sending it right back into your affected devices.
Other than that, using the snap-on type of ferrites on the power cords will help. There only difference I've seen between manufacturers are the prices.

Are you going to use an antenna tuner? If so just feed the wire into your shack and directly into the antenna tuner through a four to one balun. Works way better than a G5RV. Ingest a year's time with mine operating only an hour or so every other day or so, I have logged 67 countries. 73

If you can’t make up your mind , feed the whole thing with ladder line and put s switchable balun, 4:1 or 1:1 just before the tuner. That way you can pick what works best.

http://i1102.photobucket.com/albums/g453/KD0ZZ/4to11to12.jpg

That was my fix.

If you have room for a 204’ dipole do you have room for a delta loop with 186ft legs, you can coax feed it with a 4:1 and work all bands, 160 will have a 2:1 SWR, others will come in OK with most inbd tuners, my TS-590 works fine with it. You might have to pick your balun low SWR point adjustment if you work 6 & 10 more or 80 & 160.

Feed point is about 40 ft and other two about 30 in some trees. Recommend as high as possible but it worked with a lot of sag in it at first installation so use what you have. I would say I have low noise on 40M but higher gain than my full size vertical on 40m.

yup, put a 200 ohm resistor across the terminals if it's 4 to 1 it will show 50 ohms on the coax end if 1 to 1 it will show a 4 to 1 swr and should say 200 ohms.

Bill,

Your SWR / mis-match will vary widely depending on the band being measured at the time. IMHO, the analyzer will not help you in this instance.I think that you'll find that either the 1:1 or the 4:1 will work fine for you, and there is no "one fits all perfectly" balun. I have used both the 1:1 and 4:1 with great success. My antenna is an 88 foot long dipole / doublet up 45 feet, fed with 110 feet of 450 ohm ladder line and 10 feet or so of RG-8x between the balun and the radio. If there is any way for you to replace that RG-213 with ladder line, you might consider doing so, as that coax will induce loss in your signal. The ladder line greatly reduces this loss. The more coax you use, the more loss you'll have.

One end of the balun is coax and is connected to the test machine,,

the other end,, where you connect either the dipole or the ladder or
open line is where you connect the 200 ohm resistor.

If the balun is a 4 to 1 it will convert that 200 ohms down to 50 ohms
and you should see close to 1 to 1 swr and 50 ohms on the tester.

if the balun is a 1 to 1 version then it is just converting the balanced
to un balanced and not changing impedance's at all so at the coax end
will be 200 ohms or close to it, and the meter will say 200 ohms or at
least a 4 to 1 swr.

The resistor check is used to find out if the balun is 4to1 or 1to1 , not to check the antenna.

Joe,

Did you mean 1 to 1 is 50 ohms and 4 to 1 is 200 ohms. Also what terminals are you talking about, where the antenna legs attach to the ladderline ? Thanks

I had for quite a while a Hustler 5BTV, ground mounted, no radials. It took nothing to install and worked well. I have since sold that antenna. I now have installed a Hustler 6BTV on the exact same mount, same coax, no radials, and it's been a nightmare to get working. Measurements are exact as specified but on some bands it's SWR flat point is well below the band, some as far as 1 MHz low. I have never had that issue installing these BTV antennas. I really don't want to get in to adjusting the traps but that's probably where I'm at. The antenna is new, I opened the sealed box. Has anyone had an issue with the traps being up to a Mhz off when new from the box? I've installed several of these over the years and never had a problem.

I have had 6 Hustler BTV series antennas over the years. You may have gotten one tuned for CW Bands from the factory. Who knows? I have always (on the last 3 at least,) put it up to the spec sheet, put a antenna analyzer on it (MFJ-269,) THEN tune it. IF it is way out of bounds one one OR more freq's...you got a bad (or mis-tuned) trap. Not much else to get wrong. Especially if you put it in the exact same location. While your at it check the coax that you have with the analyzer, it could have changed...depending on where & how you stored it. If you don't have an analyzer, most ham clubs have one, or get on one of your local 2M or 75M net's. Someone close to you has one. It's just finding one! I live out in the sticks, and our local ham club (22 members) have 3 between us.

The technical answer is a 9:1 BALUN, but most 9:1's are are not true
BALUNS because they do not have a balanced 450 Ohm side, the most
common, easiest to find or make true BALUN is the common 4:1.
The match between the dipole and open wire feed line is not
important, keeping the open wire feed line fed in a balanced manor is
important, the match between the BALUN and RG-213 depends more on the
antennas impedance at the frequency in use than anything else, which
could be just about anything. That is why I recommended a 4:1 true BALUN.
Your best recommendation remains run the open wire feed line all the way
to the shack, keep the RG-213 no longer than your arm. Almost all
unbalanced tuners use the simple, basic 4:1 BALUN to feed balanced loads
'cause that works.

Hi!

I just thought I'd double check that when you say "adjust the traps" you mean loosening the hose clamps and moving trap assemblies up or down relative to the other sections, beginning with the starting points indicated in the instructions (the DX Engineering ones) . . . . Rather than doing something to the traps themselves.

I've always heard and personally experienced that the starting measurements as specified are not also the ending ones. That is, adjustments are always required . . . unless *by chance* the ones called out happen to be good for a particular site. My 5BTV required quite a bit of fiddling (not easy, as it's roof mounted). I have a 4BTV I use in the field. I use it with 8 radials and I always have to spend a half-hour or so making adjustments (so I don't take it on casual drives in the countryside).

I'll be interested in the discussion here and in how your 6BTV works out for you. By the way, is it or will you guy the thing? My 4BTV doesn't need it, but my 5BTV is too floppy at the top for my taste without guying just below the 80m resonator.

Yes as others have said get a hold of a good antenna analyzer. However before doing anything put some radials down. If the antenna is ground mounted the radials don't have to be any longer than the antenna. I have used verticals for many years and the difference between 35 radials and just a ground rod is in the order of 10db. After that, if needed you can go ahead and tune the traps if necessary. It's really easier than the instructions make it look.

Hi N0EE,
 Didn't get your name but go to the DX engeneering web site and download their info on the BTV series of Verticals. It's free and pretty much spot on. As Ray,K9RJO said. "put some radials down". 8 is a start & 16 would be better.After app. 32 the returns taper off.

 Have also used the BTV series and it came alive when I got serious about tuning it.I stopped at 52-25ft radials.

  Someone mentioned going to the Hustler ant. site on Yahoo Groups. When it was taken over by a different moderator something got screwed up and it went away. Too bad.It's always fun reading and seeing some pics. of what everyone is doing with their install.

  Hope this helps and good luck.

I hear you on having no radials in the past and having good luck with it. But I think you'd be really surprised how much difference just (8) 30ish foot radials can make. A 5BTV is designed to be used with radials. If you can't do much, just do something, as it does make a big difference. Do make sure your feed point is as low as practical to the ground as this is very important.

That said, there really isn't an way around tune ANY vertical multiband antenna; not just Hustlers. The 5BTV is a different antenna than a 6BTV, but I'll bet if you bought a new 5BTV today, you'd have to tune it as well. It's just the nature of the beast. The fact you bought one and put it in before without tuning and it was already tuned is pure luck. You should have played the lottery that day.

If you do decide to put in a few radials, you'll note that bandwidth gets narrower, but usually the SWR does get lower at points. This is a GOOD thing and its old man physics telling you your vertical is becoming more efficient much a much higher Q.

If you do put down radials which is what I suggest. Your traps might still have to be adjusted. If anyone needs the trap or trap tuning information please let me know. I used to moderate the Hustler Antenna forum and still have that info available. Yes and antenna analyzer is most useful, if you don’t have one borrow one. I happen to run a 5-BTV with minimal radials and once the antenna and the traps were adjusted I can reach Poland on 15 watts PSK.

I've used every installation info I can find, including DXE's. I did notice that one dimension is different between the factory and DXE's dimensions, by an inch. Done it both ways. I've lengthened and shortened the dimensions. Yes, one change at a time....I've been a ham for 30 years, this isn't my first go round with BTV's, but this is the first time I've gotten one that using the factory dimensions it was this far out. A full MHz low at 15meters? If I was to change the trap calibration there isn't enough room to move it down the inch or so it would take. I've been wanting an antenna analyzer, I guess this is as good of a time as any to get one.

Personally, I trust the DXE *manual* far more than I do the factory's few and **very old** pages. I'm not sure they've been updated (to take into account user feedback) at all since the 60s.

I think DXE has spent a lot of energy basing their material on actually using the antennas and getting feedback from others. The factory doesn't sell retail, so they may be unaware or otherwise deaf to user feedback. DXE is the retailer who gets customer-service calls from buyers. They also manufacture a number of add-ons and accessories for the xBTVs and I think it's reasonable to say that they know more about the things than the factory does.

I also think they did not need to produce such a manual to sell the xBTVs. You don't get the manual until you've already bought the antenna. In other words, it's not really competing--"buy from us because we've got a fabulous manual"--I think it more an example of a good-faith effort to do they're best for customers.

No, I don't own stock in DXE and I don't know anyone who has ever worked there. I just been a long-time satisfied customer.

Hi to all,
disclaimer; I have never had a Hustler Btv antenna, Here is some info I did find that may help some.

http://www.new-tronics.com/main/manual/Trap_Tuning.pdf

Here: is the tuning information from NT website:

Accurate tuning is made possible by the wide range of tuning flexibility designed into our verticals. Not only can you use the normal adjustable tubing to change resonance, but the traps themselves can be field tuned. This flexibility will enable you to achieve a good SWR even if your installation is not ideal. The trap adjustment is only used when you have exhausted the extending or collapsing of the tubing. Trap adjustment is not a substitution for a poor or no radial system.
The trap consist of three major components, Core tube, Trap can, Weather cap.
Adjusting the trap consist of moving the trap can up or down the core tubing.
Moving the trap can down the core tube raises the resonate frequency and moving trap up the core tube will lowers the resonate frequency. There is a silicone seal on the inside of weathercap so you may need to twist the trap can and remove silicone to move weather cap and trap can
1. Determine if the antenna is looking long or short
2. Collapse all 10 meter tubing
a. Is 28 Mhz SWR the lowest in the band – Long antenna
b. Is 29.7 Mhz SWR the lowest in the band – Short antenna
3. 10 meter needs to be tune to the center of the band 28 Mhz and 29.7 Mhz must be equal SWR reading with resonates being close to the center of the band
4. If the antenna is long remove trap from antenna
5. Make a reference line on the core tube below the trap can and clamp
6. Make two more lines ¼ inch down from reference lines
7. Loosen clamp and lower trap can to first mark (this will raise the resonate frequency of trap)
8. Place trap back into Antenna
9. Check SWR 28 Mhz and 29.7 Mhz must be equal SWR reading with resonates being close to the center of the band.
10. If the Band edges are not equal
11. Remove trap from antenna
12. Loosen clamp and lower trap can to second mark
13. Repeat steps 9, 10, 11 until band edges are equal (expanding tubing will fine adjust SWR)
14. After trap tuning is complete pull up black weather cap on core tube remove silicone and reapply silicone and slide weather cap back on to trap can

15. If the antenna is short use the same steps except move the trap can
up the core tube (place tubing in normal installation position
for
testing)
This procedure is used on all traps
15 meter reference lines are only 1/16 inch
20 meter reference lines are only 1/8 inch
30 meter reference lines are only 1/16 inch

I hear you on having no radials in the past and having good luck with it. But I think you'd be really surprised how much difference just (8) 30ish foot radials can make. A 5BTV is designed to be used with radials. If you can't do much, just do something, as it does make a big difference. Do make sure your feed point is as low as practical to the ground as this is very important.

That said, there really isn't an way around tune ANY vertical multiband antenna; not just Hustlers. The 5BTV is a different antenna than a 6BTV, but I'll bet if you bought a new 5BTV today, you'd have to tune it as well. It's just the nature of the beast. The fact you bought one and put it in before without tuning and it was already tuned is pure luck. You should have played the lottery that day.

If you do decide to put in a few radials, you'll note that bandwidth gets narrower, but usually the SWR does get lower at points. This is a GOOD thing and its old man physics telling you your vertical is becoming more efficient much a much higher Q.

I had for quite a while a Hustler 5BTV, ground mounted, no radials. It took nothing to install and worked well. I have since sold that antenna. I now have installed a Hustler 6BTV on the exact same mount, same coax, no radials, and it's been a nightmare to get working. Measurements are exact as specified but on some bands it's SWR flat point is well below the band, some as far as 1 MHz low. I have never had that issue installing these BTV antennas. I really don't want to get in to adjusting the traps but that's probably where I'm at. The antenna is new, I opened the sealed box. Has anyone had an issue with the traps being up to a Mhz off when new from the box? I've installed several of these over the years and never had a problem.

I had an improperly adjusted trap on my Hustler 6BTV. Adjusted the trap to the correct length and everything was fine.

One of the big problems with using a vertical 1/4 wl antennas is:
without radials they usually present a match to the feed line that is
quite close to 50 Ohms, indicating to the less technical operator that
everything is just fine, then when radials are added the match becomes
less good, lesser the more that is added. Dirt without conductive
material over it is a resistance in series with the antenna. Antenna +
resistance = load impedance.
As you add counter poise you reduce the ground loss resistance and the
antenna system impedance until you reach about 37 Ohms, which the less
technical operator sees as a bad load. (no longer matching the coax's
50 Ohms) (less good than what he started with)

Low SWR is not necessarily an indication of being tuned on your
operating frequency, a purely resistive test load is a perfect match and
they are NEVER tuned.

A good antenna analyser that can separate that ground loss resistance
from the resistance of the antenna at resonance will tell you WHERE the
antenna is tuned without error, if there is such a thing, for me I have
always used a "sweeping returned loss bridge" (with a good scope) and
the ground loss resistance, in determining antenna tuning, is
irrelevant. The only SWR indication that I ever look at is the SWR on
the meter on my transceiver.

I think the Original Poster glossed over the facts - trying to attack the problem.

What we would need to know is where in the house is your shack, what kind of transceiver are you using?

How many watts are you running?

What kind of coax are you using and what length of coax are you using?

What kind of antenna are you using, how high is the antenna, how far away from your house is your antenna.

You can add ferrite beads until the cows comes home, if you are running a G5RV and a antenna tuner and an amplifier...

Stopping RF is going to involve fixing all the mistakes before we can solve the RF problem.
Things like getting the antenna higher and further away from the house.
Making the antenna resonant or finding a resonant antenna.
Using a piece of feed line that is a half wavelength long at the desired operating frequency.

With all the electronic devices in the home today, sometimes it is very difficult to get rid of all RF, or to get the antenna high enough or to get it far enough away from the house.

I experienced multiple computer crashes trying to run digital modes with 30 - 40 watts.
Even reducing power to 25 watts would not solve the problem.
I had tried most everything common - to get rid of the problem.
I ended up moving the antenna further away from the house, putting it up higher in the sky and using a better grade LMR 400 coax...
I ended up putting up a Off-center fed dipole instead of the folded dipole - B&W 90 and that solved the problem.

I also had to get rid of the stock mouse on the computer and go to a USB wireless mouse.
The wire on the mouse was acting like a antenna and was causing the software to fail...

I live in an antenna restricted community. I am lucky to live on a half acre with 10 acres of woods available behind my house. So, I may not have the same limitations as you.

I erected a Hustler 5 BTV in the woods behind my house and documented the SWR using a AA54 antenna analyzer as I added radials. I posted the results in the Forum and as a hyperlink with this post.

You may find the results interesting.

Aaahhh...you can't put the BTV antenna ON the ground! It has to be mounted with the bottom of the antenna 20 to 23 inches above ground. This is VERY important in the tuning of the BTV antenna!

Here is a URL to the DX Engineering Instructions for the BTV Antenna Series.

http://download.qrz.ru/pub/hamradio/antenna/hustler/BTV-INSTALL-GUIDE-Rev0.pdf

With ZERO radials, your feed point antenna impedance will be close to 50 ohms. As you add more and MORE radials it will come down closer to the lowest you can get on a 1/4 wave vertical (33 ohms.) IF you correctly mount the bottom of the antenna at 2--23 inches that is.

FYI- my last 6 BTV was ground mounted w/ 1800 feet of radials. My MFJ-269 shows a feed point impedance of 34.6 ohms. (it is mounted on 6 inches of top soil over solid slate rock, (the "native" rock of Western PA!) I will tell you that if I could HEAR them, I could work them on 100 watts. (I am going to move the antenna and radials to my new QTH 30 miles north of my old QTH when it cools down in Oct.)

Move your antenna up the mounting pole to 20 inches, retest your impedance with NO radials, then with JUST 8 radials. The impedance should drop from 50 to at least 45 or less. (That will be an increase of at least 20% in power going OUT the antenna (and not heating the "fishing worms."

You are correct in that the antenna radiator and feed point cannot touch the ground. HOWEVER, the feed point must NOT be 20" above the ground. Real those instructions again. The upper bands would give you fits. The mounting pipe of a BTV series will stick out of the ground 20 off inches, but the feed point is lower than the top of that pipe and at the very bottom of the radiator. The radiator is insulated from the support pipe by plastic insulators.

The feed point of any classic Marconi vertical needs to be close to the ground, but certainly not touching it. Having the feed point 3" or so above the ground is good enough for most HF antenna installations.

My only present antenna is a 55' tall vertical with a trap at the 33'
level. The antenna was originally designed as an 80/40 meter vertical.
The designer/builder subsequently died before he could get it
manufactured for sale.

I have added a base-loading coil in order to use the antenna on 160
meters, and with my antenna coupler at the shack end of the 50 ohm coax
feeding the antenna, and with the loading coil bypassed, I can easily
load the antenna to full power on all bands, including the WARC bands
with 1:1 SWR to the rig.

At the moment, I have only 4 ea 66' long buried radials in place.

For several years I had used an empty wine bottle as a base insulator.

What is very interesting to me is that one winter, the bottle broke,
depositing the base of the antenna, with the coax connection, firmly
below ground level by at least 4 inches for several months.

Absolutely zero effect was noticed both in loading and/or operation of
the antenna.

I was amazed when on a routine inspection in the spring I found this.

I subsequently built a much more robust base insulator out of PVC pipe.

Perhaps the Hustler's are more sensitive to this type of "abuse"?

I can't speak to your unusual situation. Strange indeed.

The best way I have heard a vertical and it's ground plane described is to think of it as the two halves of a dipole. What happens when you separate the two halves of a dipole? You reduce coupling and it becomes less efficient and the SWR changes dramatically. Same thing with the vertical and ground plane. Increasing coupling greatly improves Q of the system.

John, Here is where you should follow these instructions, from New Tronics:

Trap Tuning

Accurate tuning is made possible by the wide range of tuning flexibility designed into our verticals. Not only can you use the normal adjustable tubing to change resonance, but the traps themselves can be field tuned. This flexibility will enable you to achieve a good SWR even if your installation is not ideal. The trap adjustment is only used when you have exhausted the extending or collapsing of the tubing. Trap adjustment is not a substitution for a
poor or no radial system.
The trap consist of three major components, Core tube, Trap can, Weather cap.
Adjusting the trap consist of moving the trap can up or down the core tubing.
Moving the trap can down the core tube raises the resonate frequency and moving trap up the core tube will lowers the resonate frequency. There is a silicone seal on the inside of weather cap so you may need to twist the trap can and remove silicone to move weather cap and trap can
1. Determine if the antenna is looking long or short
2. Collapse all 10 meter tubing
a. Is 28 MHz SWR the lowest in the band – Long antenna
b. Is 29.7 MHz SWR the lowest in the band – Short antenna
3. 10 meter needs to be tune to the center of the band 28 MHz and 29.7 MHz must be equal SWR reading with resonates being close to the center of the band
4. If the antenna is long remove trap from antenna
5. Make a reference line on the core tube below the trap can and clamp
6. Make two more lines ¼ inch down from reference lines
7. Loosen clamp and lower trap can to first mark (this will raise the resonate frequency of trap)
8. Place trap back into Antenna
9. Check SWR 28 MHz and 29.7 MHz must be equal SWR reading with resonates being close to the center of the band.
10. If the Band edges are not equal
11. Remove trap from antenna
12. Loosen clamp and lower trap can to second mark
13. Repeat steps 9, 10, 11 until band edges are equal (expanding tubing will fine adjust SWR)
14. After trap tuning is complete pull up black weather cap on core tube remove silicone and reapply silicone and slide weather cap back on to trap can
15. If the antenna is short use the same steps except move the trap can up the core tube (place tubing in normal installation position for testing)
This procedure is used on all traps
15 meter reference lines are only 1/16 inch

20 meter reference lines are only 1/8 inch
30 meter reference lines are only 1/16 inch

Once your satisfied with the tuning, ya’ll will need to reseal the traps with NON-ACIDIC Silicon. DX engineering has it. If you use regular silicon from the local DIY store the trap will corrode and ya’ll will be replacing traps or buying a new antenna in a short period of time.

I found this statement particularly amusing and educational.

I simply have never been able to understand how any vertical can operate even remotely efficiently without a radial system of some sort.

As another member mentioned, the best "view" of a vertical, IMHO, is as a dipole folded at the center.

Perhaps in those cases in which operation of a vertical is attempted withOUT a radial system, the coax feeding the system and everything attached to it at the shack end is enough so that it appears as at least one radial...

Ken, In some cases the metal mounting post serves as a ground and some think it will suffice as a radial of some sort. I disagree. My view on a vertical antenna is the radial system is the other half of the antenna "folded dipole" and some a better than none at all. Depends on soil conditions and earth conductivity.

Again, that is the way I see it also. Even ONE real radial is far better than none at all. At least you would have a full dipole then.

I have seen a map of the soil conductivity covering the U.S. and Canada. GOOD soil conductivity is very, very rare all over the North American continent. Most soil conductivity is very poor.

Thanks, Greg.

I can attest to the "very poor ground" statement. When I first moved to California in 1987 I had a 5BTV and was renting a home while looking for a place to buy. I temporarily drove a pipe in the ground and mounted the BTV to the stake - could not put down any radials. The performance was, shall we say - "sucky". Now, 27 years later, I have that same antenna installed in the back yard, but this time with 40 radials of various lengths snaking through the grass. I used the DX Engineering tilt-over base along with their radial plate. Performance has been very good, allowing me to work a lot of DX and US stations. In addition, for 17 of my 27 years in CA, I had that antenna mounted on the top of my single story home in Martinez, using the same tilt-over base and radial plate, but using the DXE tuned radial package. Very, very good performance on 80 and 40 meters. Bottom line - this is a great antenna for folks on a limited budget and small property, but to make it sing, put down radials.

I now have an extensive radial field. That effort didn't do squat for me. I finally "calibrated" the traps and it is usable.I just planted $100 worth of copper in the ground and it didn't do anything positive on transmit, maybe receive but certainly not on transmit. Until I Calibrated the traps, I was pissin' in the wind. Of course, your mileage may vary. Thanks for the suggestions.

>
Well, it's quite likely that the radials *and* the trap tuning will make
it a better performer than just the tuning alone. You may have pretty-good
soil conditions such that adding radials didn't seem an improvement.

It's also likely the radials have lowered the antenna's launch angle, and
that's always good. You wouldn't know that's so until you've operated with
it for a while and notice improved DX performance.

33235. 5 Band Portable Vertical - QST article from a few months ago ...

Yahoo group: ham-antennas (2014)
Date: 2014-07-17 03:59:40 UTC
From: Robert Ahrens
Topic: 33235 Message: 33235

Hi everyone,

I spent many hours over the past couple weeks building the 5 band vertical which was recently described in QST. I am surprised at how long it took to assemble all of the parts! But I feel really good about the antenna.

I did make one significant change to the original design. I added a junction block at about 84" above ground level and made three loading coils. The first - for 20M - is simply a jumper. The antenna is 1/4 wave on 20 and it should work just fine. The 20M "coil" is simply a place holder, connecting the top and bottom sections of the 20M radiator.

The second coil resonates the 20M element on 30M, and the third coil resonates it on 40.

Interestingly (though perhaps not really a surprise) the 10, 12, 15 and 17 resonances do not seem to be much affected by plugging in the 30M or 40M coil.

I will be using 12 16' radials, 2 25' radials and 2 33' radials, for a total of 16. Hopefully that will be sufficient to give my TS-440 a voice when I am portable in Park City, UT for the next month or so.

I was able to bring everything into resonance with my mfj analyzer. Much trimming and measuring. But that was the fun part, right?

Anyway, I thought I would share ..

You measure about 0.3-0.4 volts dc?!?

What metals did you use ?!? (maybe you built a big earth "battery")

Dissimilar metals can give up a small dc voltage

(3 copper and 3 iron nails plus some fruits can feed a small radio!!!)

The same thing

Only difference is that in a telecopic antenna there are contact "sliders" added in each connection ... and upper end is crimped somewhat (to prevent pulling out the sliders)

It may not be pure D.C.

It could be distorted and asymmetric A.C. with a D.C.
component.

It is worth checking with an ungrounded oscilliscope.

Hi,
Antenna work is always fun! Your choice for radial count, and length,
seems like a reasonable starting place. I am going to have to go look
up that article now...

33240. Ladderline length

Yahoo group: ham-antennas (2014)
Date: 2014-07-17 11:28:35 UTC
From: gatewood_bill@...
Topic: 33240 Message: 33240

I am making a dipole and feeding the first part with 450 ohm ladderline than a 1 to 1 balun to rg-213 coax. I have to do it this way. Can I make the ladderline any length I want to or is there a certain length. Multi band dipole 204' long, flat top. Ladderline coming down tree. Thanks

33241. Re: [ham-antennas] Ladderline length

Yahoo group: ham-antennas (2014)

From: Alex Netherton
Topic: 33240 Message: 33241

Well if you can't bring the coax into the shack directly to the tuner, then I suppose you should look up G5RV antennas. The G5RV needs no balun and should not have one.
Lots of people do not like the G5RV. I prefer the antenna described with ladder line all the way to the shack. Mine works great.

Bill

Generally speaking the antenna can be fed with any length of ladder line. Some lengths may present a complex impedance at the feed point that on some frequencies is beyond the range of impedance that the your tuner is able to match. There are so many variables (Antenna height, length, ground conductivity) that predicting which frequencies might present a matching problem is nearly impossible. If it were me I would use an extra 10' or so of ladder line, if I then found a band that the tuner couldn't tune I would cut off short sections of the extra 10' till I found a sweet spot., logic being it is easier to cut 6" than it is to keep splicing in longer sections

Hi,

Keep length of the coaxial line at 1/2 eclectic wave for the lowest band
Ladder line in theory could be any length but in practice AVOID 1/4 electric wave length.
Personally I would suggest ladder 1/2

Best regards Hiro m0hdd

Bill,

I agree with Dave. I have a 102-ft version of your setup, and it works fine. I use it as a doublet on 80 to 30, and as a T on 160, loading it against a ground plane. I have 46 states confirmed on LoTW on 160 with it, and got my DXCC using it. (Yours should load up on 160 as a doublet, due to its size.)

I would add a couple of things. First, bring the window line as close to the tuner as you can. If you only have an inch of coax between the balun and the tuner, that would be good. (Some tuners have the balun built in, and that would be even better.) There will be a high SWR on the coax (that your tuner will tune out), and this SWR will cause losses in the coax if it is a long run. I have about three feet of coax, and that seems to be acceptable.

Also, you might consider a 4:1 or 9:1 balun. I tried both, and one was better on some bands, the other on other bands. I went with the 9:1 because it was easier to mount and has screw terminals on the top. See which one gives you the lowest SWR on the bands you are most interested in.

Try to keep the window line at least 6" from the tree trunk and branches. In the rain, the wet wood can effect your SWR and losses.

GL. I'm sure you will enjoy the antenna.

About tuners with the balun built in, what would be the expected
losses due to the balun working on high SWR?
I understand baluns are designed to work with somewhat fixed
impedances.

Bob,
Nice job, would you give the QST article reference?
I would like to look it up.
Thanks

From: soona4sail@...
Topic: 33240 Message: 33248

Google "Feedline lengths to avoid" and you will find several usefull links on the subject of ladderline lengths.

I,m not sure why you want to combine ladderline with coax It can cause more problems than not.

Even Mr Varney, creator of the G5RV, admitted in a later article, that his design for the G5RV was completely wrong, and the 30 ft length of ladderline, followed by coax, was very inefficient, and a waste of time.

He revised his design, and suggested the G5RV was best fed with about 80 ft of balanced (ladderline) directly to a tuner. No coax at all.

He was describing the doublet.

Good luck.

Yeah, I knew I should include the reference details ... I just did not have them when I did my post.

The details are in the May 2014 QST, starting on page 36.

I used 1.25" PVC pipe about 3" long for my coil forms. I drilled near the end of the forms and press fitted and glued banana plugs. I then drilled holes about 1/4" apart along a line drawn between the banana plugs. These holes were provided to simplify my experimental coil-winding efforts.

I was fortunate to find solder-less banana plugs with a screw to clamp in the lead wire. They also had a hole drilled through them so that another plug could be plugged into the side. This is a fairly common feature these days, though the screw clamp was new to me. These were pretty cheaply made plugs, but seem adequate to the task. I would never use them on a good piece of test equipment!

Anyway, the arrangement made for an elegant plug-in coil form and empirically finding the appropriate number of wire turns was much quicker than the trimming of the other elements had been!

I drilled through the length of a 2" block of wood and stuck two of the plugs into the holes. The holes in the sides of the plugs then provided sockets for my plug-in coil forms, with the added benefit that the width between the holes was adjustable, just in case my quality control was less than perfect between my coil forms. :-)

I glued (JB Weld) the block of wood to a short piece 3/4" PVC pipe which then slips over the WonderPole and slides down to a level above the guy ring and convenient to my reach (I am about 6' tall).

The author's method of using the little hooks (cut from credit card scraps) seems only semi-functional to me. Whenever I had to telescope the pole down to adjust things, at least one of the hooks would come undone and it was sometimes inconvenient to sort things out. There must be a better - more secure - way to attach the elements to their supporting strings. Perhaps a fishing spinner would be a better choice. I will fiddle with that in UT when I set it up for real and will have days to mess with it in place.

I also think that I will tape the top of the 20M element to the top of the pole rather than use the hook/string/rubber band idea. We'll see ...

Your mileage may vary, and there are certainly many ways to accomplish the same things. I will say, the antenna tunes up nicely and I cannot see any reason to think it will not match the performance of any single band

vertical with similar ground system.

From: Scott Myers
Topic: 33251 Message: 33252

For a desktop switch with one rig and 4 antennas, the Alpha Delta is as good as anything, unless you want something fancier or panel mount. Then you have MFJ, Diamond, Jetstream and probably more going to lower cost (but not as well built as Alpha Delta). Jetstream probably costs the least. Then there is a high end German manual switch that Array Solutions carries. Then the next thing is remote switches, which start costing quite a bit.

33253. How to diagnose a bad trap on a tribander?

Yahoo group: ham-antennas (2014)
Date: 2014-07-18 01:52:58 UTC
From: wb2aio@...
Topic: 33253 Message: 33253

My Hygain Explorer 14 has suddenly stopped working on 15 meters. 10 & 20 are fine. My first thought is that a trap has gone bad. It has given years of flawless performance until now. The only thing I can see from the ground with binocular's is that the coax feed line looks taught on it's way from the mast to the balun, but it may have always looked that way when turn to 176 deg., as I seldom beam in that direction. (chasing the w1aw/4 SC now) Going back to the normal polar path didn't correct the problem. Plus, if it pulled the PL259 apart, it'd show on 10/20.
So how does one figure out a trap problem. I assume it is normally the driven element that goes bad.

If you haven't seen the Mosley paper on diagnosing trap issues, it's at this link. http://www.mosley-electronics.com/pdf/checkingtraps.pdf

Your trap system is different, of course, but a lot of the principles are the same.

If you have or can borrow an antenna analyzer it would be interesting to see if that trap is resonating above or below 15 or just not at all. If 20 is working right, a failed 15 meter trap probably has to offering the same loading to the element as a good one, which I suppose can happen with a shifted resonance if the inductor ain't affected but the internal capacity is.

Good luck, hope it doesn't need to come down. I just finished rebuilding some failed Mosley traps to make a Field Day antenna, and it was kinda fun after the first one :(

Hi Tony:

Based on my personal experience, you are headed in the right direction looking toward Alpha Delta. I have three four position. One is a four position that I am trying to get a console container for to feed to the antenna tuner. The other two are the console models that switch radios and antennas around. The console model is the same switch as the $99 model, which means that the console is a $50 add on. I honestly thought I might have been a bit over the top buying it. Within five minutes of putting it in, I changed my mind. It is heavy, it is stable and does not walk around, it is angled well so you can see what you are switching from and to. It also has ground lugs. Well worth the extra bucks.

33259. Tuning a coax J-Pole

Yahoo group: ham-antennas (2014)
Date: 2014-07-18 03:41:59 UTC
From: gtbecker@...
Topic: 33259 Message: 33259

Hi, folks. I'm a longtime ex-ham who never lost the antenna-building bug, whose roof is littered with wire and, mostly, VHF verticals - but I also stream VLF (spherics) and fast-scanned marine VHF.

I've built many coax J-Poles over the years, supporting them in fiberglass tubing that holds them vertical well. They've made fine receive antennas.

Recently, I replaced a commercial VHF whip on my boat with one of these home-brew J-Poles, but found the VSWR was ~3:1. Rather than rip the heatshrink off, dismantling, and experimentally cutting and reassembling the antenna as required, I found that I could apparently tune the antenna by sliding a wrapped ~2"-wide section of several layers of aluminum foil around the heat-shrunk coax near the base of the J. I was able to find 1.2:1, and locked the foil in place with another layer of heatshrink.

Does this low VSWR (measured at the antenna) necessarily mean the antenna is radiating well, despite the unusual tuning method, or can I be fooled?

Hi Tony:

Based on my personal experience, you are headed in the right direction looking toward Alpha Delta. I have three four position. One is a four position that I am trying to get a console container for to feed to the antenna tuner. The other two are the console models that switch radios and antennas around. The console model is the same switch as the $99 model, which means that the console is a $50 add on. I honestly thought I might have been a bit over the top buying it. Within five minutes of putting it in, I changed my mind. It is heavy, it is stable and does not walk around, it is angled well so you can see what you are switching from and to. It also has ground lugs. Well worth the extra bucks.

I have a 75 meter dipole in trees strung from trees East & West. It is about 45 Feet off the ground at each end and 25 feet off the ground in the center.

Each end had an L drop of 2-3 Feet. So most of my pattern is North & South but what do the two drops do?

Richard

As Don said: It helps "match" (lower the SWR,) from the antenna to your rig. That little L is less than 3% of the antenna length.
Just make sure that the end's are no where near anything conductive. (The voltage at the ends of the dipole will be quite high.

Is what good?

That most of your power is straight up?

That all depends on where you want to communicate with. If you want to communicate with rather close in people. Then YES. but if you want far away places, then NO.

My opinion is: Nuten' honey, save tune it to it's current frequency.
If you can restore the "end droop" and bring up the center, where the
current is highest, you will help yourself.

The one tree is locust and I have broken off two branches already.

I have the most pressure on branch it can handle.

The coax in the center weights it down.

A line in each tree over a branch with a pulley's one on each end at about
45-50 feet.

The wire goes through the pulley to and insulator and cord to the ground.

I can raise and lower all parts The pulley's are at the highest I can get
them without using a sling shot.

Tuned 1.2 - 1 at 3.99

With the right conditions you can get kilovolts even from QRP power levels.
It's a matter of where you look, and what the impedance is at that point.

At the far ends of a dipole, the voltages are quite high.

Don't forget, a kilowatt is only 3.2 times as much voltage as 100 watts.
It's not a huge difference.

Most of the radiation from a dipole comes from the middle third to half of
the antenna. The ends contribute relatively little to it. If the parts of
the ends that drop are only 2-3 feet, I'd say their effect would be
insignificant.

You aren't sending *all* your signal straight up, but that is where the
best signal goes from a lower dipole on 75 meters. Many people strive for
that to happen; it's called NVIS. But there will be radiation out towards
the horizon too; just not as much as if your dipole was up at a hundred
feet or more elevation.

Andy

I think you will find, the closer to the ground a Voltage antenna
gets, the more power is being conducted into the dirt. A good resistor.

No it does not mean the antenna works well

Remember a dummy also has a low swr but does not radiate well

... if your low swr comes from losses then the antenna does not radiate well ... coax j pole can have a loss of 10 db or more when using coax as the quarterwave part!!!

33277. Re: [ham-antennas] Ladderline length

Yahoo group: ham-antennas (2014)
Date: 2014-07-18 22:09:51 UTC
From: Alex Netherton
Topic: 33240 Message: 33277

Like the fellow said, Varney (G5RV) even admitted that balanced line clear to the tuner was a better way to go. The balun is not needed until the balanced line gets to the tuner. Many MFJ tuners have a balun built in.

I am running a 102 foot center fed with balanced line into the shack. It is from MFJ, the MFJ-1777 (too hot to get on the air to make my own). In the last year since I got active again, not getting on every day, just piddling around, I have worked 67 countries, and states all over. Generally, if I can hear them, I can work them. For pileups I have the help of an old Heathkit SB-200. Tuners here in the shack are a LDG AT-100ProII autotuner, and I have been known to put the 4:1 balun on with a double PL-259, or just a 3 foot piece of coax. Also a MFJ-993B autotuner, which has a balun in the box. Works great. The main tuner here now, since high power came in is an old Heathkit SA-2040, which has a built in balun. (I had to replace the balun since some modder had taken it out, but I digress.)

If you use a tuner, and it has a balun built in, you are golden. If you use a balun, put it as close to the tuner as possible, and make it a 4:1. If you use a random bit of balanced line and put in a balun and hope it will tune without a tuner, then you need to do some homework, because it will not tune. Tuners for 100 watts are quite affordable, especially used. 500 watt tuners are a little more, even used. 1000 watt tuners are up there.

Yes, the gain will drop and the increased coupling may reduce the SWR bandwidth.
Of course you could add a 20 meter director inside the reflector and have a bi-directional radiation.
Close spaced beams and quads usually are driven and director combination.

Tom

Assuming that this was an optimized design to begin with and if you did nothing to the length of any of the loops. then over all performance would be degraded, for gain, F/B and SWR

With a lot of modeling you could probably arrive at new lengths that would in some cases only be down a few tenths of a d/b on some of the lower bands and might even be an improvement on some of the higher bands. Not a trivial exercise in terms of the time investment.

There are a lot of very capable FREE modeling programs out there such as MMANA-GAL and this would be the perfect project for YOU to learn on :-)

I think you are very clever, I also think you did what goes on inside
of waveguide when it is "dent tuned." You added a "lump" of capacitance
at the right distance to effect the natural resonant frequency. I
believe you are golden, but only you can compare it's performance to
another of your creations to be very sure.

Hi,

Regarding to the balun and ATU's
My experience shows that balun should be on INPUT instead of OUTPUT terminals of ATU
But let's say it clear, there is NOT only one right option.
Balun can be placed in different place of feeding line between TX and ANT if you do proper antenna system engineering.

> feed line and it can be a lot.

Thank you to all for the input, especially Kd0zz.

Unfortunately I cannot support the centre feed point as it transverses my undulating concrete tile roof, so some sag there will have to be :(

The only other option is to attach the centre feed point of the G%RV onto one of the upright poles and then run both 'sides' of the G5RV parallel to one another, using drilled PVC conduit as spacers to keep them apart, until I can attach the end of each 'side' to an insulator tied to the second pole.

I have a 'sneaking' suspicion however that this will yield the antenna dead, as it is essentially a long-wire radiating into the ground leg of the antenna.

I have done some Google searches and have read the ARRL Antenna Book and noting a mirror image of the antenna in the ground, although I just don't understand how a signal transmitted bounces off the ground, real or antenna ground, especially from a horizontal piece of wire that has a doughnut radiation pattern around the length of the 'live' wire?
What length Is the radius of the doughnut, of course in free space since there are no physical barriers i.e. roof tiles. I would assume that this would be determined by the frequency but what formula would be used to work it out?

I realise explaining these is complex and if you can put me onto a website/s that can explain it with diagrams, please pass them on.

Appreciated and 73 de ZR1HPC

Yes. What you will have is not an antenna, but a transmission line.
The two branches being parallel -- think of it -- how is it different
from a length of ladder line? Answer: no different. To be more physical,
recognize that there are currents in each leg, and that these currents
are of the same magnitude, but of opposite direction, hence as the
currents change, and each leg generates a field, the fields cancel.
Now, you can get some radiation from such a beast if you can induce
"common mode current" like the currents in the outside of a coax shield.
But that's not going to be reliable.

In fact, one of the textbooks I've seen on antennas uses this as an
example: you start with a parallel transmission line, and slowly open
out the arms, first a narrow V shape, then an obvious V, finally the
arms are in the shape of a dipole. As this process proceeds, you are
looking at the field created, always at right angles to the final dipole,
i.e. in the direction of the original transmission line. You look at
the filed parallel and perpendicular; you take a vector sum, the result is
what results from the radiation.

In your case, you'd be better off just running one half the transmission
line; the resulting antenna is an "End Fed Zepp", discussed in all the
right books and manuals.

> I have done some Google searches and have read the ARRL Antenna Book and
> noting a mirror image of the antenna in the ground, although I just

This is, I believe, a mathematical convenience. Go look in a mirror.
Is there really another you, your mirror image, in the space behind
the mirror? Your cat, being a more rational beast, believes there is,
and will check that space for the second cat.

> don't understand how a signal transmitted bounces off the ground, real

Do you know how light bounces from a mirror, or is refracted in a lens?

Radio waves are light waves. (Not "are like", but "are".) It's the very
same sort of process.

> or antenna ground, especially from a horizontal piece of wire that has a
> doughnut radiation pattern around the length of the 'live' wire?
> What length Is the radius of the doughnut, of course in free space since
> there are no physical barriers i.e. roof tiles. I would assume that this
> would be determined by the frequency but what formula would be used to
> work it out?

Take a second look at that doughnut, at the graph of that doughnut.
The coordinates are angles (assuming a three dimensional graph), and
something else, what you are calling distance. It's not a distance,
though! It's far-field strength. So these graphs are really in what
is called "phase space", not "physical space". Imagine we have a rod
of metal, one end of which is in a flame, the other in a bucket of ice.
We could make a plot of distance along the rod, the temperature of the
rod, and perhaps add a third axis, time since flame turned on. We'd get
a nice surface, that thermodynamicists could calculate for us using the
"Heat Equation". But there would be no *physical* structure corresponding
to the "shape" plotted.

Moral: always check what the axes are in a plot of anything!

> I realise explaining these is complex and if you can put me onto a
> website/s that can explain it with diagrams, please pass them on.

The Antenna Book does it fairly well. If you're "technical", a college
textbook on "Antenna Theory" will do it in bloody detail. The usual
texts are two, one by Krause (a ham/professor) the other by Balanis.
If you like differential equations and so on, these are for you.
Cheap editions can be obtained from India. (Due to a court case, this
is now 100% legal in the USA, I expect that in ZA they can also be found
as a matter of course at booksellers, or can be ordered from India.)

33285. Modifying a Jetstream JTV680

Yahoo group: ham-antennas (2014)
Date: 2014-07-20 04:11:40 UTC
From: kb8dns@...
Topic: 33285 Message: 33285

I have a poorly working Jetstream JTV680, It is only partially working and I would like to redo the load coil so that it does work. Granted the antenna was received for a low price, I swapped a SW receiver for it, I do not mind changing it to work better.
Talking about adding a larger coil and or some sort of capacitor so I can tune the antenna with better results. I know I may get some 'flaming' from this but I know most HAMs are a curious bunch and more than happy to modify, build, alter and change things for the better!
I have some older Cushcraft commercial head end cable TV yagis for near the 220 mHz band and 6 meter band.... soon to be amateur antennas!

Thanks for any input! 73 Rod KB8DNS

Tony:

I totally back up your statements. The guy at Balun Designs, (Bob, I believe) is a class act. I have talked to him twice and learned a lot. I have a minor issue with a forty meter dipole not getting better than 1.5:1. I put my AA54 analyzer on it, and then compared it to a 20 dipole that was flat. I spit out all of the readings on the rig expert yahoo group asking for interpretation without an answer for several days. Out of a bit of frustration, gave BD a call.
Within a very few minutes of conversation I realized that my thinking was reversed. The twenty meter antenna actually needs a little help, and after hanging up the phone, I realized the slightly elevated SWR on the 40 with the balun had two issues that I need to address that have nothing to do with the balun....I will report my findings later after I pull the antenna down and change the feedline elevation and make one other change. I am very optimistic the SWR will go flat.....Yep I would buy another one.

From: wb2aio@...
Topic: 33253 Message: 33289

Hi,
I wanted to give an update to my antenna problem. First I want to thank those who responded. Good ideas and thoughts. If you take a look on my QRZ page(W2NK) and click on the photo, you can see my set up. (Only no snow now:)) Got my 32' ladder out, which reaches to the edge of the dormer when on my deck, and went up and climbed my tri-pod to the antenna. 1. coax wasn't taut, just looked that way from ground, so wasn't coax pulling out of ballun. 2. coax is good, no shorts and not open (couple trips up and down to check, it would be nice to have a helper) 3. visual inspection shows nothing amiss. 4. all connections are tight. 5. no bird nests, etc. 6. swapped the coaxs with the D3W above it and went down and checked again and is working fine, but so is the D3W. 6. Both antennas are working.

The only thing I can see is that the drain holes in the traps aren't perfectly in the 'down' position, but more like 160 deg if 180 is perfectly down-this happened when I assembled the beam originally up there and didn't have a good reference to what exactly is down working on the slant of the roof. The solution for this will to be to take a step ladder up there and with the antenna pointed due west or east, will be able to reach the traps on the driven element and be able to take them off to see if insects have used them their nesting areas and to turn them so the drip holes are perfectly 180. Perhaps rain water got in the traps and were shorting them?
I'm also thinking it isn't the antenna having a problem at all but something with my rig (TS570) and it was infected with some gremlin or just wanted to take some time off. The rain seeping into the traps is still a thought and just my being up there and time and movement allowed it to drain out. But Saturday afternoon, we had a nice heavy all day shower which put 0.9 inches in my rain gauge and it still worked fine. (Sorry drought stricken W6's)
So for now, will leave it alone, but will leave the ladder in place in case the problems shows again and then look at taking a step ladder up there, but that doesn't appeal to me as to get to the trap, means the ladder would be on the steep sections of roof out at the end and I'm getting old and not quite so foolish as in younger days...
73,
Kathy w2nk

33290. RE: [ham-antennas] Putting up mast/pole. Need some suggestions

Think of your mast pole as being a simple lever.
The longer you make the lever, the more leverage you will have.
Having 40' of pole, or even 20' - a simple bucket of cement could never hold it in a storm, very bad idea.
At the very least, you need to dig a hole 4' deep, cement a larger tube in the cement. Slip the mast pole into the tube in the cement.
Fiberglass poles have no real strength, the only thing they are good for is a field days operation, where the antenna is only used a day or two a year.
Leaving it up all the time, the tube is going to deteriorate in time and fail.
You can buy Rohn push up masts economically, or you can use conduit - 1 1/4 semi rigid and guy wires.
Do not use rope - not a very smart idea - the rope will stretch when it gets wet and will sag.
For what you wish to do, you need to put up some tower.
Any other advice would be irresponsible.
Proper grounding of the pole is a must in Florida - lot's of lightning storms, and you need to use Polyphasers before the feed line comes into the house.
There is no cheap solution to your situation.

What does this have to do with a Rest Home that does not allow antenna's?
If the owner of the Rest Home says no! Then the answer is NO!
A retired / disabled person is a Guest / Resident of the home.
You have no right to demand special accommodations for your hobbies.
There is no way for sure that anyone on this forum could guarantee without a doubt that using radio equipment to transmit in a close proximity to other old people with Pacemakers and other life sustaining equipment, would not be harmed by the RF emitted from the antenna.
There is a point in time when everyone has to give in to the fact that when you are placed in a rest home you no longer are in control of your situation and for some people, their ham radio career is over.
Buy the guy a handheld radio and let him play CB with his local ham radio buddies.
Or, if he belongs to a club, have the club members pick him up, haul him to the club shack, and let him operate occasionally, when it is convenient, and then take him home.

> ... coax j pole can have a loss of 10 db or more when using coax as the quarterwave...

Why is that? A severe mismatch at the high-impedance end? Is this same loss present in receive?

I built a dual band J-pole out of some scrap twin lead and it doesn't work worth ... I have a Sinclair 222 http://www.sinclairtechnologies.com/catalog/product.aspx?id=332 left over from commercial days and hooked it up to my station to see if I could hear the local repeaters any better. Leaning on my garden shed, I get better signal and the expected SWR (3:1).

Just for the heck of it I tried on UHF and I have no reflected power at all. I'm using a Bird 43 and the appropriate slugs. I don't have modeling software but I expect the pattern is 'interesting'

These things are tough as nails, we dropped one 80', straightened the elements, put it up and it ran the life of the project, 20 years at an Sub-Arctic mine.

I have built many J-Poles using 300 ohm TV lead in and ½ copper tubing. I put a cap on the small J and solder a bolt & nut on it for tuning.

The most troubles was the dual bender. I have an MFJ antenna analyzer to show me where to place the taps for 50 ohms and tune the tuning slug.

There are many types and patterns out there

Richard

I'm having trouble understanding what is the "strange behavior" you speak of.

Is it that the J-pole you built didn't work? Is it that the commercial 2-element antenna with gain, outperforms a 1-element antenna without gain? (A J-pole is essentially an end-fed half-wave, fed with a quarter-wave matching stub, so one would expect approximately 0 dBd gain because it is the same as a half-wave dipole). Is it the fact that the Sinclair works out-of-band? Or that it loaded up fine on the 3rd harmonic too?

Did you tune the J-pole, or find the optimum attachment points? Did you use a balun? Or try reversing the leads? What was the J-pole's SWR?

How was the J-pole made "dual band"? Is there a trap or phasing stub for the higher band?

Regards,
Andy

Bravo, David. I totally agree with you regarding Mr. Bosak. I moved my parents into a assisted living complex a number of years ago to be nearer us and yet still provide them some independence. This is a very traumatic experience for senior citizens. This complex was very progressive in its' views towards seniors. They polled the residents to see if there was interest in forming a ham club at the complex and, if not, were amenable to allowing the hams there to operate their rigs, if they ran 100 watts or less and had antennas that were of the mobile whip variety, or inconspicuous thin wire. Granted, they did not allow beams. LOL. I have been a landlord for many years, and generally a happy tenant is a good tenant. People like Mr. Bosak just foster animosity between senior citizens and the facilities developed especially for them to make their remaining years as enjoyable as possible. Many of these individuals are home bound and need social interaction with the outside world. Dave, WA6TXU.

I agree with the pomposity of the original response, but whatever..

I did want to dispel a common misconception about pacemakers and other implantable medical devices. Just being in close proximity to most electromagnetic fields will not adversely affect implanted medical devices in any way. Implantable pacemakers and defibrillators CAN be affected by strong magnetic fields because most are built with a magnetic switch to shut off defibrillation therapy or modify pacing therapy in the presence of a strong magnet placed very close (<6 inches) to the implant site. Extremely strong electrical fields or strong rapidly changing fields can induce currents in pacing leads that can lead to localized heating of tissue at the lead tips, which can adversely affect performance.

With that being said, working with HAM HT units is generally safe if the antenna is kept beyond 6" from the device for low-wattage (~5W) outputs. Increased distance is recommended as output wattage increases for HTs and base installations. In no instance can the implanted device be reprogrammed just by RF. There are detailed handshaking protocols that have to be completed before a device allows reprogramming of internal parameters. The rare reprogramming of an implanted device usually happens when the patient is exposed to fields seen in MRI machines and the device resets, although the newest devices are being shielded against even those extreme fields.

As long as you're not standing right next to a high-output antenna, there wouldn't be any issues. For more information, check out the Electromagnetic Compatibility Guide found at http://www.medtronic.com/patients/bradycardia/living-with/questions-answers/index.htm. Other manufacturers have similar guides.

Tom asked:

"Is this same loss present in receive?"

Any loss in transmit is always present in receive too.

Some loss in receive might not matter at HF, but it does matter for VHF.

I'll add my 2 cents:

I am 75, not the best of health and I have visited several Senior Assisted Living Centers and they do not allow antennas on their facilities. For that reason I will not move into one unless I require assistance in surviving. If I am that bad off I can't operate my rig anyway.

I have instructed my family that when I can no longer operate my ham rig (CW only op) you can put me in a "rest" home and my complete station will be donated to the Arizona Science Center's amateur radio station K7ASC for their use (http://www.qrz.com/db/W7ASC).

A retired / disabled person is a Guest / Resident of the home.
You have no right to demand special accommodations for your hobbies.
There is no way for sure that anyone on this forum could guarantee without a doubt that using radio equipment to transmit in a close proximity to other old people with Pacemakers and other life sustaining equipment, would not be harmed by the RF emitted from the antenna.
There is a point in time when everyone has to give in to the fact that when you are placed in a rest home you no longer are in control of your situation and for some people, their ham radio career is over.
Buy the guy a handheld radio and let him play CB with his local ham radio buddies.
Or, if he belongs to a club, have the club members pick him up, haul him to the club shack, and let him operate occasion ally, when it is convenient, and then take him home.

Hamradio is NOT an occuption that stops on retirement, HAM RADIO is a HOBBY, and has little or nothing to do with CB radio, which was actually an off shoot of ham radio about 30+ years ago.
To deprive a person of a legitimate hobby for very little cause is herendious, and you sir are ignorant, .
You also have no knowledge of the hobby, before you make comments do your self a favour , research what you are commenting on.
Down here we call it "foot in mouth disease", you sir have managed not 1 but both feet in yours.

I am the Moderator, 1 of 2
I am the Owner of this List, also 1 of 2

This is NOT political
This is NOT religious
This is Life in the U.S.A. I did not see anything that was not
basicly true. I did see a LOT of opinions.

The man or corporation that owns a facility generally makes the
rules, which cannot be unlawful,
but can be controversial.

These posts have been a classic example of (a little raw) of
understandings, misunderstandings.
and feelings on both sides. I spent 42 years in government, owned
rental property,
spent military time, etc. I have come under folks laws and rules
every day of those 42 years.

So, the postings have been a little rough, but folks, you may not
like what you're hearing
or the way it was written, but my only complaint is the word
"a..h...", and the concepts of control
by an owner, state, local or federal entity (meaning the laws or
owners rights) was what was discussed.

However, bad language or offensive words, subjects mentioned on the
rules that are posted once a month,
are my major concern. More of that will result in removal/moderation
at the least.

So I would watch the language, or sanctions will be applied.

Obviously you (jerrybosak@...) don't know anything about rest homes. The residents are in THEIR home and the staff sees to their needs. Think of it as a restricted access of your apartment by those that can take care of the needs you cannot. The price paid for residency is not cheap, for the costs are very high. Some facilities make special attempts to meet residents' needs, but some seem to ONLY be there for profits. Properly worded requests to caring staff will be seen to within allowable restrictions, exceptions do get made at times. I do hope that this ham can get his RF fix and continue in some way or another! Maybe there needs to be a retirement community, like some military service communities, where like minded people (and they can be of any age) can use a cooperative station(s). Any philanthropists out there want to build a community around ham antennas?

Hi ALL:
If this subject was covered in the past please give me direction to same regarding building a wooden tower to mount antennas by this group.

I am looking to build a wooden tower upon which to mount some antenna's. I would say the that it would be on the order of what you see in those old western flicks, of the little windmill H2O pump tower.

I am thinking a 40' structure would be acceptable or even 60' may be better.

Thank you!

John KB3SVJ

OK I like the 40 Ft Mine is a 33 Ft Crank up and easy to work on. How do you plan to mount antennas and work on it ?

You’re going to climb it? What are you going to do in 10 years paint it, it may have dry rot?

It may be unsafe in 10 years?

Richard

If you can get cheap in a usable height ... then rebuild it in 10 years and put the old one in your fire place :-)

Hmmm with the right wood used ... it would sure hold longer then 10 years

They around here have been using a LOT of laminated (Glued) wood power poles. A quick Google search shows one company with ones that go as high as 165 feet! and 165 feet dead end UNGUYED!!! where it has to hold back thousands of pounds of the wire tension!! WOW!!!

33314. Re: [ham-antennas] Re: NEW Challenge Rest home restricted use HF antenna

Yahoo group: ham-antennas (2014)
Date: 2014-07-22 13:27:23 UTC
From: Timothy-Allen Albertson
Topic: 33069 Message: 33314

To deprive any person of something because of a disability or health issue
is wrong
unless it is absolutely necessary and only to the extent that such
restriction is the
the most narrow one most necessary.
